SECTION IV THEORY OF OPERATION

4.1 INTRODUCTION

The KNS 81 is a computerized area navigation unit capable of calculating and displaying course data to a programmed waypoint. The KNS 81 requires an external DME for distance information. The unit can be operated as a VOR, an RNAV, or an ILS (Glideslope optional). It can also be operated as a TACAN if it is a -3X flavor and used in conjunction with a TACAN receiver. It is possible to store up to nine waypoints (-0X, -18 flavors) or 10 waypoints (-1X, 2X & -3X except -18 flavors) in the KNS 81. Waypoint data is retained during power off conditions.

4.1.1 BASIC VOR PRINCIPLES

4.1.1.1 General

The basic function of VHF Omnidirection Range (VOR) is to provide a means to determine an aircraft's position with reference to a VOR ground station and also to follow a certain path toward or away from the station. This is accomplished by indicating when the aircraft is on a selected VOR station radial or by determining which radial the aircraft is on. A means to differentiate between radials and identify them is necessary. For this purpose, advantage is taken of the fact that the phase difference between two signals can be accurately determined. The phase difference between two signals which are generated by the VOR station is varied as the direction relative to the station changes so that a particular radial is represented by a particular phase difference. Refer to Figure 4-1. One non-directional reference signal is generated with a phase that at any instant is the same in all directions. A second signal is generated with a phase that at any instant is different in different directions. The phase of the variable phase signal is the same as the phase of the reference signal only at the 0° radial (North). As the angle measured from the 0° radial increases, the phase of the variable phase signal lags the phase of the reference signal by the number of degrees of the angle from 0° . The reference and variable phase signals, which are 30Hz voltages, are carried by RF to make radio transmission and reception possible. The VOR receiving equipment must separate the 30Hz reference and variable phase signals from the RF carrier and compare the phase of the two signals. The phase difference is indicated on a course indicator or RMI.

4.1.1.2 VOR Generation

The VOR electromagnetic field is composed of the radiation from two ground based antennas radiating at the same carrier frequency. The first is a non-directional antenna radiating an amplitude modulated carrier. The frequency of the modulating signal varies from 9480Hz to 10,440Hz back to 9480Hz 30 times per second. That is, a 9960Hz subcarrier amplitude modulates the RF carrier and is frequency modulated by 30Hz.

The second antenna is a horizontal dipole which rotates at the rate of 30 revolutions per second. The dipole produces a figure 8 field pattern. The RF voltages within the two lobes are 180° out of phase with each other. The RF within one of the lobes is exactly in phase with the RF radiated from the non-directional field. The rotating figure 8 pattern reinforces the non-directional pattern on the side (see Figure 4-1). This results in a cardioid field pattern which rotates at the rate of 30 revolutions per second, the rate at which the dipole antenna rotates.

The signal at an aircraft within radio range of the VOR station is an RF carrier with amplitude varying at the rate of 30Hz because of the rotation of the cardioid pattern. The carrier is also amplitude modulated at the station by the 9960Hz signal which is, in turn, frequency modulated by the 30Hz reference signal so that it may be separated from the 30Hz variable phase signal.

4.1.2 BASIC AREA NAVIGATION PRINCIPLES

When the KNS 81 is in RNAV mode, the navigation computer must solve navigation problems. A typical problem is shown in Figure 4-2.

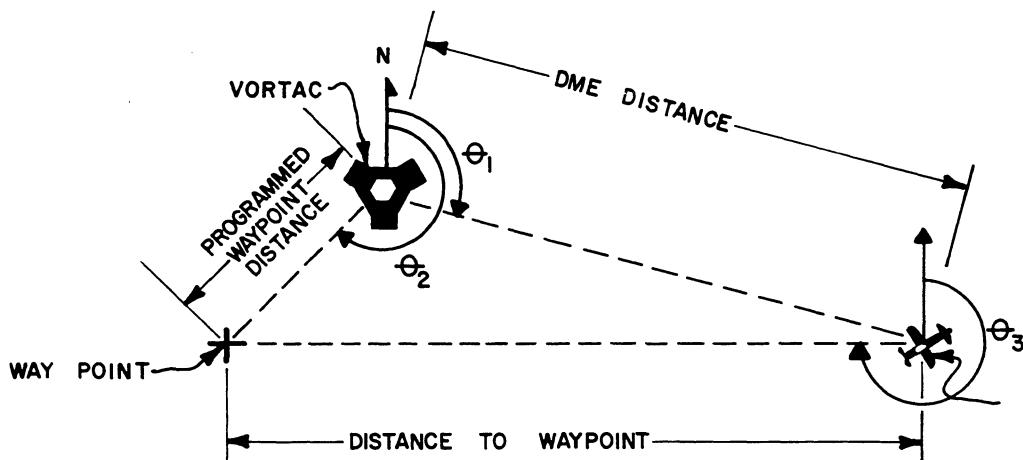

FIGURE 4-2 TYPICAL AREA NAVIGATION PROBLEM

θ_1 (pronounced Theta one) represents the angle from the VORTAC to the aircraft, the received radial. θ_2 represents the angle that the waypoint is from the VORTAC. Two sides and the included angle are known enabling the triangle to be solved. Trigonometry is used to find the unknown distance to waypoint and θ_3 . The computer then compares θ_3 to the selected course angle obtained from the OBS. The distance deviation from the selected course is calculated from the distance to waypoint and the angular deviation from selected course.

Course deviation is computed by solving another triangle formed by the distance to the waypoint, θ_3 , and the OBS angle selected by the pilot. The solution is made for course distance deviation rather than course bearing deviation as in conventional VOR converters. Refer to Figure 4-3.

Course distance deviation is commonly called constant course width. It is advantageous because it presents the pilot and autopilot with position error in constant terms which are easier to interpret. The large deviation errors common to VOR converters at station passage are also eliminated by the constant course width feature.

The TO/FROM indication is derived by comparing the phase difference between θ_3 and the OBS angle. If this difference is $+90^\circ$ or less, a TO indication is given. Likewise, if the difference is greater than $+90^\circ$, a FROM indication is given.

4.1.3 BASIC LOCALIZER PRINCIPLES

The localizer facility provides a visual display of the aircraft's position relative to a straight approach line to the runway. The ground based localizer antenna system generates two patterns. Refer to Figure 4-4. One pattern is directed toward the right side of the runway, the second to the left. The two patterns have the same carrier frequency but different audio modulating signals. The pattern to the left of the runway (in normal approach) is 90Hz amplitude modulated which the pattern to the right is 150Hz amplitude modulated. The ratio of 90Hz and 150Hz audio, after demodulation, is dependent only upon the position of the aircraft within the patterns. The patterns are adjusted so they are of equal strength on a vertical plane extending out from the runway centerline. When the aircraft is on this plane, the 90Hz and 150Hz voltages will be equal.

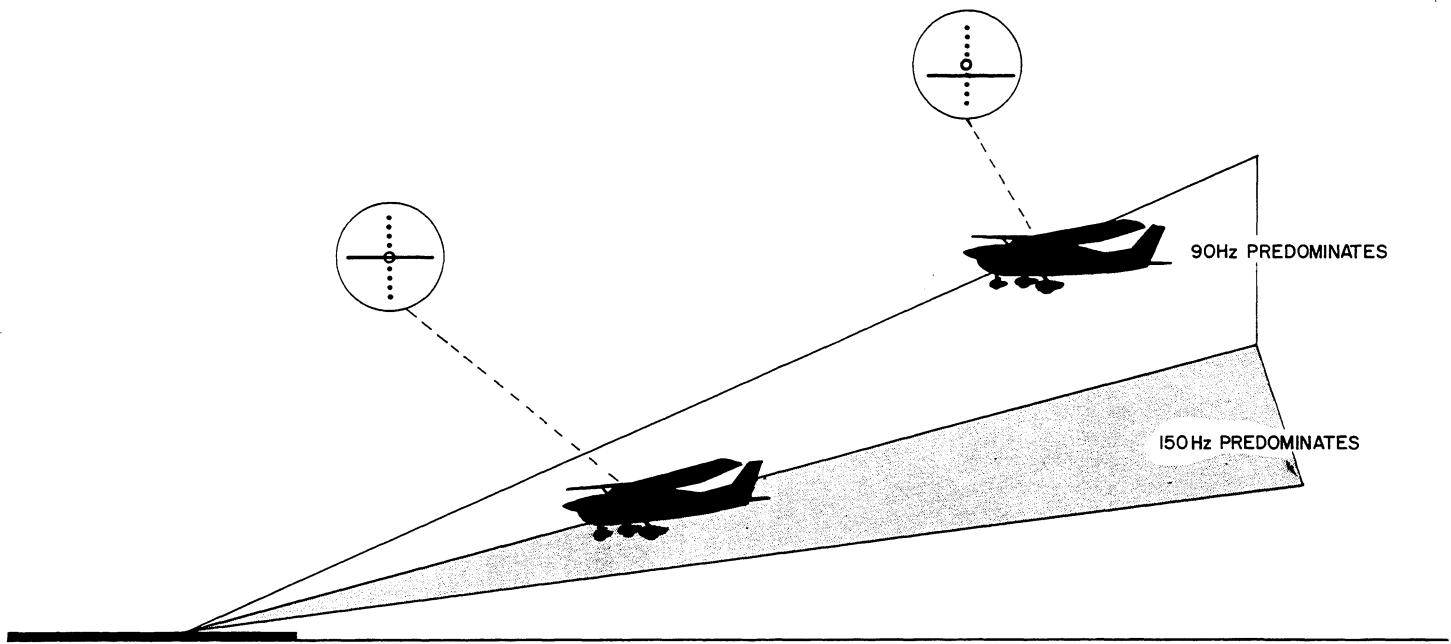

FIGURE 4-5 GLIDESLOPE PATH
(Dwg. No. 696-1539-00, R-0)

4.1.4 BASIC GLIDESLOPE PRINCIPLES

The glideslope signal is radiated by a directional antenna array located near the approach end of the runway. The signal consists of two intersecting lobes of RF energy. The upper lobe contains 90Hz modulation and the lower lobe contains 150Hz modulation. The equal tone amplitude intersection of these two lobes form the glide path. A typical glide angle is 2.5 degrees. If the aircraft is on the glide path, equal amplitudes of both tones will be received and the deviation bar will be centered. If the aircraft is above the glide path, 90Hz modulation predominates and the visual display is displaced downward. If below the glide path, 150Hz predominates and the display is displaced upward. Refer to Figure 4-5.

There are 40 glideslope frequencies in use today with a channel separation of 150KHz and each of these is paired with a localizer frequency as shown in Table 4-1.

4.2 SIMPLIFIED CIRCUIT THEORY

Figure 4-6 shows the simplified block diagram of the KNS 81. The individual blocks are discussed briefly in this section. For a more detailed discussion, see Section 4.3, Detailed Circuit Theory.

4.2.1 POWER SUPPLY (SIMPLIFIED)

The power supply in the KNS 81 employs a ringing choke regulator to produce the following DC voltages: +192.0V, +13.5V, +5.0V and -26.0V. The ringing choke regulator enables the KNS 81 to run on any voltage from 11 to 33VDC with no modification or rewiring. Also, power consumption of the KNS 81 (15 watts maximum) is virtually independent of input voltage.

4.2.2 NAVIGATION RECEIVER SIMPLIFIED CIRCUITRY

4.2.2.1 Receiver

The navigation receiver board block diagram is shown in Figure 4-8 of this section. The receiver is a single conversion superhetrodyne design with a monolithic crystal IF filter. The receiver generates VOR or localizer composite for the converter section. Audio is separated from the composite and amplified.

4.2.2.2 RF Section

The RF section of the receiver has two poles of selectivity both before and after the RF amplifier. The RF stages and VCO are varactor controlled from the synthesizer tuning line.

4.2.2.3 Synthesizer

The synthesizer uses a universal synthesizer to generate a frequency 11.1MHz below the received frequency. The synthesizer receives its tuning information digitally from the microprocessor and its reference frequency of 12.8MHz from a crystal oscillator.

4.2.2.4 IF Section and Audio Section

The RF signal from the preselector and the local oscillator frequency are mixed in a dual gate DMOS FET. The 11.1MHz mixer output is selected with a crystal filter and amplified by two AGC controlled IF amplifiers. The detected output contains VOR/LOC composite and audio. The audio between 350Hz and 2.5KHz is amplified in the audio section to produce 50mW into a 500 ohm load. The 1020Hz ident tone is suppressed when the ident filter is switched into the circuit. VOR/LOC composite is buffered and sent to the converter.

4.2.3 CONVERTER SIMPLIFIED CIRCUIT THEORY

The navigation receiver used in the KNS 81 receives the radio frequency energy transmitted by a VOR or LOC ground station. This radio frequency energy is demodulated and the modulation information is sent to the converter. The VOR/LOC composite signal from the navigation receiver consists of the 9960Hz frequency modulated reference phase signal and the 30Hz variable phase signal if a VOR frequency is selected. The VOR/LOC composite signal will consist of 90Hz and 150Hz if a LOC frequency is selected. Refer to Figure 4-9 for a block diagram of the converter. The TACAN signal which can be used by the KNS 81 is actually a synthesized VOR composite produced by the TACAN receiver. It contains equivalent signals and levels to those produced by the Navigation receiver.

4.2.3.1 VOR Operation

If a VOR frequency is selected by the navigation receiver, the KNS 81 separates the variable phase 30Hz signal from the 9960Hz frequency modulated reference by passing the buffered VOR composite through a 30Hz bandpass filter, I302A and associated components. This variable phase filter removes all the reference phase modulation from the variable phase signal.

The buffered VOR composite is also fed to the FM discriminator, I304, which recovers the 30Hz reference phase signal from the frequency modulated 9960Hz signal.

The filtered 30Hz reference phase signal from I305B is fed to the rotor winding of an OBS resolver.

By turning the OBS knob, the pilot turns the azimuth card and the rotor of the resolver. Output of the stator windings of the resolver is amplitude dependent upon the mechanical position of the resolver rotor. By connecting both stator windings to an R-C network, R337, R338 and C316, an output voltage that is constant amplitude but phase dependent upon the position of the resolver rotor is derived. This constant amplitude variable phase signal is amplified by a low pass amplifier, I307A and then again by a PLL 30Hz bandpass filter, I308. The output of the reference and variable bandpass filters are squared by I303 and I306. The variable signal is additionally filtered by PLL I329. The variable and OBS square waves' phase are compared to the reference square waves' phase (I313) which results in a pulse whose width corresponds to a specific angle. These pulses are sent to the computer where the D-bar and TO/FROM information is calculated. This information is then buffered and sent to the indicator.

4.2.3.2 Localizer Operation

When an ILS frequency is selected, circuits within the converter are switched to the configuration required for localizer operation. LOC composite from the input buffer passes to the bandpass filters. The center frequencies of filters have been changed to 90Hz and 150Hz by switching in additional components. The FM discriminator is bypassed through an FET switch.

Steering information in localizer mode is obtained by comparing the output levels of the two bandpass filters. The difference in amplitude of the two filters is obtained by a localizer detector circuit which essentially subtracts the level of 90Hz from the 150Hz. This process is accomplished by rectifying the positive half of the 150Hz sine wave and the negative half of the 90Hz sine wave and filtering out the resultant DC component. This DC component is used to control the D-bar driver.

Localizer flag indication is obtained by summing the levels from the bandpass filters. If the summed voltage from the bandpass filters falls below a usable level, the output voltage of the flag amplifier will not be great enough to pull the warning flag from view.

TACAN Operation

- | | |
|-----------------------|---|
| (-3X flavors) | The change from VOR/Loc to TACAN is automatic when one of the three TACAN modes is selected. I300 and I301 comprise a switching circuit which selects whether the Navigation receiver or the TACAN receiver is the input to the converter. The switching circuit is controlled by the microprocessor. After receiver selection is completed the converter operation is identical for VOR and TACAN. |
| (-0X and -1X flavors) | By means of an external switch the switching circuit (I300 and I301) could be controlled manually. With the advent of the TACAN version however, this capability is not used. |

4.2.4 DISPLAY SIMPLIFIED CIRCUIT THEORY

4.2.4.1 Data Timing

The display used on the KNS 81 is time multiplexed. Only one of eight sections of the display is lit at any one instance. The section being lit is changed about every millisecond. The 125Hz display rate is fast enough to produce a steady image to the eye. The block diagram in Figure 4-10 shows how the data is moved to the correct position for displaying.

4.2.4.2 Display Circuit

The display of the KNS 81 is operated primarily by the PIA Johnson counters, I317 and I319 in both the anode and cathode driver sections and are controlled by the microprocessor via the PIA interface. One of the Johnson counters, I317, operates the anode driver I318 such that each anode is switched on in the proper sequence. Information is given to the cathode drivers in two forms. First, data from the microprocessor via the PIA interface is fed to the cathode drivers I322 and I327. These cathode drivers send the data to the display digits. The PIA controls the multiplexing of the data so that the correct data is displayed at the correct place on the display. Secondly, the PIA in conjunction with a Johnson counter, I319, controls the message sent to the display and also controls the current programming circuitry for the message cathodes of the display. The message data is sent directly to the cathode drivers, I321 and I323, which sends the message to the message words on the display. The Johnson counter is also interfaced with the message lines from the PIA to current programming circuitry. This circuitry controls the amount of current to be sent to each individual cathode so as to maintain a constant current flow through the entire display. This keeps all digits and message words at a uniform brightness.

4.2.4.3 Dimming Circuit

Automatic dimming is controlled with a photocell and a light dimming circuit. Dimming is accomplished by varying the duty cycle of the current programming circuitry of the cathode drivers.

4.2.5 GLIDESLOPE SIMPLIFIED CIRCUIT THEORY

4.2.5.1 Receiver

The glideslope signals in the range of 329.15MHz to 335.00MHz are coupled from the antenna to the first RF amplifier. The desired signal is amplified in this tuned RF amplifier and coupled to the second tuned RF amplifier. The signal again receives amplification. The combination of the two RF amplifiers provide the necessary preselection before passing onto the active mixer. The signal from the universal synthesizer is then mixed with the incoming signal producing the intermediate frequency of 33.3KHz. The signal is now passed into the first IF amplifier where the signal strength is increased. The signal is then passed through a three section low pass elliptic filter which removes the unwanted frequencies from the IF signal. The IF signal is then directed through two more IF amplifiers before being applied to the detector. The detector removes the 150Hz and 90Hz modulation from the IF signal. There are two signal paths, one goes to the AGC circuitry and the other to the deviation converter.

4.2.5.2 Deviation Converter

The composite 150Hz and 90Hz signal is now applied to the course width amplifier which has a gain less than one. From here the composite signal is filtered to 90Hz and 150Hz components by the use of two active filters.

The two separated signals are passed through their own individual peak detectors and are then summed and fed through a deviation-bar driver. The DC voltage from the D-bar driver is proportional to the amount of voltage created by the presence of various amounts of 150Hz and 90Hz signals.

The outputs of the 90Hz and 150Hz active filters are also passed into two more peak detectors. There is a separate peak detector for each frequency. The outputs of the two peak detectors are summed and fed into the flag driver. Again the DC voltage output of the driver is used to drive a visual indicator which provides a warning indication when the signal strength is too weak, or when one or both of the two modulation components is absent.

4.2.6 MICROPROCESSOR SIMPLIFIED CIRCUIT THEORY

The microprocessor system processes and distributes data to various parts of the KNS 81. Some of its various functions are:

- A. Receive front panel switch information
- B. Send data to be displayed
- C. Tune receivers
- D. Calculate the aircraft's position from DME and converter information
- E. Provide indicator drive (TO/FROM, flags, D-bar deviation drive, and mode indication)

The microprocessor system block diagram, Figure 4-12, shows that a few basic parts make up most of the system. These include the microprocessor (MPU), permanent memory (ROM), temporary memory (RAM), and input/output buffers (PIA).

The microprocessor receives instructions from the permanent memory called the read only memory or ROM. Examples of instructions include storing and retrieving data into RAM, outputting data to the PIA's, and performing calculations upon sets of data already inside the processor.

The PIA's or peripheral interface adapters are input/output interfaces to the outside systems. The PIA's can receive information from the processor, latch it, and output it continuously; or they can receive information from external systems and send it to the processor.

Information transfer throughout the computer system is synchronized by 895KHz supplied by the MPU.

Via one of the PIA's, waypoint information is stored and retrieved from a non-volatile memory (EAROM).

A DME Interface circuit takes information from the DME and passes it to the microprocessor. The calculated distance is then relayed from the microprocessor back through the interface circuit to the DME.

To insure proper operation of the microprocessor two reset circuits are employed. The first detects a lost program condition and the second checks for an unacceptably low voltage level. Should either condition occur the microprocessor will be periodically reset until the problem is resolved.

4.3 DETAILED CIRCUIT THEORY

4.3.1 GENERAL INFORMATION

This section provides a detailed description of the circuit operation. Timing diagrams, circuit schematics, and individual components are referred to extensively as an aid in understanding the theory.

The following numbering sequence is used in the KNS 81:

<u>BOARDS</u>	<u>COMPONENT DESIGNATORS</u>
Power Supply Board	100 - 199
Switch Board	200 - 299
Converter/Display Board	300 - 499
Computer Board	500 - 599
NAV Receiver Board	600 - 799
Glideslope Board	800 - 899

4.3.2 POWER SUPPLY

4.3.2.1 Ringing Choke Regulator

DC current flowing through the primary windings of the power transformer, T100, is alternately switched on and off by Q102. When the primary current is on, energy is stored in the transformer's magnetic field. When the primary current is off, the energy is dissipated by current flowing in the secondary winding. Four taps on the secondary windings are then rectified and filtered to produce the various DC voltages required by the KNS 81.

Voltage regulation is achieved by varying the duty cycle of the switching signal that drives Q102. The base frequency of the power supply is 20KHz. By controlling the amount of time Q102 is turned on, the amount of energy to be transferred to the secondary of the transformer is controlled. The +5.0V output of the power supply is divided down by R100, R125 and R101 and compared to the +5.0V reference output of I100. The DC output of the comparator, I101C, is then used to control the duty cycle of I101D, a comparator which compares the DC level to a triangle wave produced by I101A, R113 through R117 and C110. The output of I101D is a square wave which is coupled through emitter followers Q100 and Q101 and then used to drive Q102. The voltage regulation compensates for changes in input voltage or power supply load. R125 is adjusted to obtain +5.0V at TP518.

CR101 senses the voltage of the +13.5 volt line. If the line exceeds +15.1 volts, the voltage at pin 8 of I101C will increase causing the comparator to regulate the supply to the correct voltage. I101B is a current limiter and a soft start to limit power supplied to the transformer. Voltage is sensed at R124 which is compared with the voltage which appears at pin 7 of I101B.

4.3.3 NAV RECEIVER DETAILED CIRCUIT THEORY

4.3.3.1 RF Preselector

The RF signal input (108.00MHz to 117.95MHz) is coupled into the first filter pole (C601, CR600 and L600) by L615. This pole is varactor tuned by CR600. The signal is then coupled into the second filter pole (C606, CR601 and L601) by C603. This pole is varactor tuned by CR601. The RF signal is then capacitively coupled into G₁ of the RF amplifier Q600, a dual gate DMOS FET.

R603 and R605 bias G₁ of Q600. The RF AGC is applied to G₂ of Q600. The voltage at G₂ will be approximately 7VDC (full RF gain) from no signal to 2uV (hard) input. At 2uV input the RF AGC will attack and the AGC voltage will decrease thereby reducing the RF amplifier gain according to the level of the input signal. At high RF input levels, the G₂ voltage maybe as low as 0VDC.

The amplified RF signal is coupled into the third filter pole (C614, CR602 and L603) by C613. This pole is varactor tuned by CR602. The signal is then coupled into the fourth filter pole (C618, CR603 and L604) by C616. This pole is varactor tuned by CR603. The RF signal is then coupled into the mixer (Q601) by C619.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

4.3.3.2 Mixer

The filtered and amplified RF signal is applied to G₁ of Q601. The buffered VCO (local oscillator) signal is coupled into G₂ by C621. G₁ and G₂ of Q601 are biased by R614 and R618. The RF signal is mixed with the local oscillator signal to produce the 11.1MHz IF frequency.

4.3.3.3 IF

T600 impedance matches the 11.1MHz mixer output into the monolithic crystal filter, FL600. FL600 determines the receiver bandwidth and rejects unwanted frequencies of the mixer output. T601 impedance matches the FL600 output into the differential input of the first IF amplifier, I600. T602 impedance matches the output of I600 into the differential input of the second IF amplifier I601. I600 and I601 are AGC'd to provide the correct IF gain.

4.3.3.4 Detector

The 11.1MHz IF signal is fed into the active detector by T603. Q602 and R626 develop the base bias for Q603. With the collector shorted to the base, Q602 is functioning as a diode which has the same thermal characteristics as Q603. On positive swings, Q603 will conduct and on negative swings, Q603 will cut off less, thus providing detection. R627 and C632 remove the IF signal frequency leaving the composite and audio signals to be processed by the convertor and audio sections.

4.3.3.5 IF AGC Amplifier

The DC component of the composite signal is sent through a buffer (I603C) to the AGC amplifier, I603B. The IF AGC circuit takes the instantaneous DC component of the composite signal and integrates it to produce the IF AGC. The integrator is I603B and uses C634 and C635 as the feedback path. A low voltage from the integrator will demand near maximum gain from I600 and I601. A higher voltage from the integrator will produce a lower gain from I600 and I601.

4.3.3.6 RF AGC Amplifier

The signal from the integrating amplifier, I603B, is sent to an inverting amplifier (I603A and associated components). The amplifier has two inputs, the variable or IF AGC voltage from the integrator and the reference or RF AGC set. The RF AGC is adjusted so the amplifier attacks at 2uV (hard) RF input. At low signal inputs, the RF AGC output voltage applied to G₂ of Q600 will be high and the gain of Q600 will be at or near maximum. At higher level input signals, the RF AGC voltage will be lower and the gain of Q600 will be lower.

4.3.3.7 Audio Pre-Amp and Ident Filtering

The composite signal from Q603 is buffered by I602A and associated components. I603D and R633 are used to adjust the composite output level. The signal is then filtered by a noise limit circuit (CR606, R658-R661, C640 and C641) and an elliptical high-pass filter network (I602B and associated circuitry). The elliptical high-pass filter has a 3dB break point at 300Hz. I602B's output is coupled by C639 to give the volume control the AUDIO OUT signal.

I602C and D, along with their associated circuitry form the ident filter. This filter is active whenever the ident line is shorted to the volume control AUDIO OUT line. The ident filter is a gyrator type of circuit and is active at 1020Hz.

4.3.3.8 Audio Amplifier

The audio signal which comes from I602B is passed through the volume control and then to the audio amplifier. R699 and C679 along with R698 and C680, filter the audio signal before it is amplified by I605. The output of I605 is used to drive a center tap transformer which impedance matches to a speaker.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

4.3.3.9 NAV Synthesizer

The local oscillator signal is developed and frequency controlled by a phase locked loop (PLL). The heart of the PLL is the VCO (Q610 and associated components). The VCO is a Colpitts design with L612, CR609 and C668-C670 being the major frequency determining components. The VCO is capable of changing from 96.9MHz to 106.85MHz (11.1MHz below the RF signal) by varying the DC voltage or varactor CR609. The output of the VCO is capacitively coupled to the buffer stage (Q611 and associated components). The buffer eliminates frequency pulling of the VCO by the load. The buffer supplies the VCO frequency to the mixer (Q601 and associated components) and to the synthesizer buffer (Q606 and associated components). The synthesizer buffer provides additional isolation between the universal synthesizer (I604) and the VCO. The output of the synthesizer buffer drives the prescaler input of the universal synthesizer. The synthesizer receives a 12.8MHz reference frequency input derived from Y600, Q604, Q605 and associated circuitry. The synthesizer divides the 12.8MHz reference by 256 to obtain a 50KHz reference. The prescaler input is also divided by an integer, referred to as N_T , to obtain 50KHz. N_T is determined by the serial channeling data on pin 7 of the synthesizer. The synthesizer then phase/frequency compares the reference and prescaler inputs. If the frequency of the prescaler is low with respect to the reference, the synthesizer produces "up" pulses on pin 3. If the frequency of the prescaler is high with respect to the reference, the synthesizer produces "down" pulses on pin 2. The "up" and "down" pulses are fed to the charge pump (Q607, Q608, Q609 and associated components). The duty cycle of the "up" or "down" pulses determine the length of time that Q607-Q609 are turned on or off. The length of time that Q607-Q609 are turned on or off determines the average charge on C664. The voltage on C664, in turn tunes CR609, thus determining the VCO frequency. Hence, the loop is completed. C681-C683 and L610 filter the 50KHz reference from the control voltage. C685, C686, R685, R684, R687 and L611, all provide additional filtering and isolation of the DC control voltage. This control voltage also tunes the preselector via varactors CR600-CR603.

4.3.4 CONVERTER DETAILED CIRCUIT THEORY

4.3.4.1 Input Buffer

The VOR/LOC composite is capacitively coupled through C341 and C340 through I300D to I302, the input buffer. Resistors R301, R302 and variable resistor R303 control the gain of the amplifier. The non-inverting input of the amplifier is tied to V_{ref} through R305, giving an output signal with an average DC level of V_{ref} . Since the amplitude of the 30Hz FM component is determined by the deviation in frequency and not the amplitude of the 9960Hz subcarrier, the gain adjustment can be used to balance the VAR and REF sine wave signals.

4.3.4.2 Bandpass Filter and Squaring Amp Detailed Circuit Theory

The bandpass filters utilized in the KNS 81 are of the multiple feedback type. Figure 4-13 shows a typical multiple feedback bandpass filter.

In VOR operation, Q1 is turned off and looks like a high impedance which effectively removes R2 from the circuit. Center frequency of the circuit is dependent upon the parallel combination of R1 and R3 along with R4, C1 and C2. Center frequency is set to 30Hz by varying R3. Output of the filters is capacitively coupled to the squaring amps which function as comparators referenced to 4.8V. As the input sine wave swings through its midpoint, the output changes state. Positive feedback through C329 and C332 eliminates multiple triggering.

In localizer operation, Q1 will be saturated and R2 will be in parallel with R3 to change the frequency of the filter. In the 150Hz BPF, a resistor is switched in parallel to R4 to obtain equal Q's in both filters. The microprocessor ignores the output from the squaring amplifiers in the localizer mode.

30Hz Variable Phase-Locked Loop Filter

I329 and associated circuitry form a phase-locked loop (PLL) bandpass filter. The VCO output of the PLL filter (Pin 4) is a square wave whose phase is the same as the input. The output is fed into a phase comparator (Pin 3) that compares the input and output. Any phase difference changes the pulse width on Pin 13. R441, R443, C360 and C361 form a low-pass filter which averages the voltage from Pin 13. On units with Mod 8 installed or KNS 81 units KPN, 086-4010-80 and above, the low pass filter is replaced by an active low pass filter consisting of I1001, R1001-R1004, C1001 and C1002. The active low pass filter provides a more stable average DC voltage representing the phase shift of the 30Hz variable. This provides better filtering for rotor modulation. This changes the control voltage to the VCO (Pin 9). R440, R442 and C359 determine the natural frequency of the PLL.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

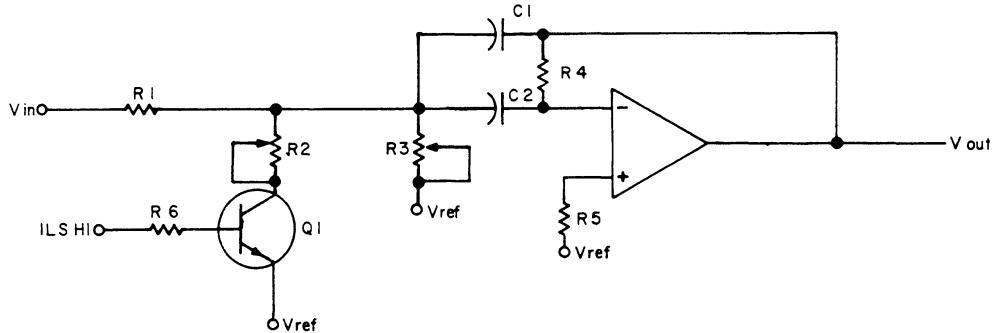

FIGURE 4-13 BANDPASS FILTER

4.3.4.3 FM Discriminator

The REF 30Hz FM modulation on the 9960 subcarrier is detected with a PLL. The PLL consists of a phase comparator, low pass filter, VCO, and source follower amplifier. R320 and C311 form the low pass filter for the input VCO voltage. R317, R319, variable resistor R318 and C310 are timing components that determine the natural frequency of the VCO. The phase comparator and VCO are located in I304. The 9960Hz signal from the input buffer I302B is passed through a series resonant circuit consisting of L304 and C306. The signal is limited by Q301 and CR301 and applied to pin 14 where it is phase compared to output signal of the VCO. The phase comparator output is a square wave whose average value is related to the difference in phase between the two signals which in turn is related to the difference between the input frequency and the natural frequency of the VCO. Since the signal into I304 is varying at a 30Hz rate, the average value of the phase comparator output will vary at a 30Hz rate. The source follower amplifier within I304 buffers the low pass, filtered phase comparator output. The buffered output is applied to the REF 30Hz BPF to remove noise.

4.3.4.4 30Hz Resolver and Low Pass Filter Detailed Circuit Theory

Selected course information is obtained through the use of an external OBS resolver. The resolver is a transformer with two secondary windings (stators) physically displaced 90° from each other. The amount of signal transferred from the primary coil (rotor) to each of the stators depends upon the pilot's selected setting of the rotor position. When the rotor is located so as to give maximum coupling into one stator winding, the other winding has minimum coupling. The phase shift network consisting of C316, R337 and R338 causes one signal to be phase shifted 45° leading and the other signal to be shifted 45° lagging. The vector addition of these signals results in a constant amplitude 30Hz signal with a shift in phase that depends on the OBS setting.

The low pass amplifier I307A amplifies the signal and reduces high frequency noise. Gain of the amplifier is determined by R339 and R340. The low pass filter causes about 6° of lagging phase shift.

4.3.4.5 OBS 30Hz PLL Filter

I308, I307B and their associated components form a phase-locked loop (PLL) bandpass filter. The VCO output of the PLL filter (pin 3) is a square wave whose phase differs 90° from the input. If for some reason the phase difference is not exactly 90° , the squarewave output of the phase comparator (pin 2 of I308) will have an average value which differs from the average value at pin 3. I307B will integrate this difference and change the control voltage of the VCO (pin 9). The frequency of the VCO will change slightly until the VCO output is 90° out of phase with the input. Noise is reduced since the integrator will not respond rapidly to the input voltage.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

I307B and associated components form the integrating amplifier. I308 is a phase comparator and voltage controlled oscillator (VCO). R347, R348, variable resistor R349 and C320 determine the range of frequencies that the VCO will lock on. The resistance divider consisting of R341, R342 and R343 determine the reference voltage for the integrator. Variable resistor R342 is used to make minor adjustments in phase shift.

4.3.4.6 Converter Timing

The aircraft's angular position is perceived as a phase difference between Reference and Variable square waves and Reference and OBS square waves. The microprocessor, however, interprets the length of a pulse as being an angle. This circuitry, therefore, converts the phase difference into a pulse of specific length and sends it to the microprocessor upon request.

I313B is a flip-flop set by the reference square wave and reset by the variable square wave with the resulting output pulse being equal in length to the phase difference. C337 and R399 form a differentiator which changes the variable square wave to a spike to ensure the proper length of the output. I313A is the flip-flop which compares the reference square wave to the OBS square wave with C339 and R400 forming the differentiator for the OBS square wave. The reference square wave is then sent to the microprocessor as an interrupt. Using VOR control 1 and 2, the microprocessor can ask to measure one of the three pulses. If VOR control 2 is low, AND gate I314D will be disabled and I314C enabled allowing only the reference/variable pulse to pass through OR gate I316C. A high on VOR control 2 will do the opposite and allow only the reference/OBS pulse to pass. VOR control 1 controls the final output to the microprocessor. A low on VOR control 1 disables AND gate I314A and enables I314B which will allow only the reference square wave to pass through OR gate I316B to the microprocessor. A high on VOR control 1 allows only the pulse selected by VOR control 2 to pass through the OR gate to the microprocessor.

4.3.4.7 Localizer Deviation Detector Detailed Circuit Theory

In the LOC mode, the difference in signal levels between 90Hz and 150Hz signals is accomplished by subtracting the level of the 90Hz signal from the 150Hz signal. CR311, R372, and variable resistor R370 rectify the top half of the 150Hz waveform to about the "virtual ground" (4.6V) at pin 2 of I309A. Likewise, CR312, R373, and variable resistor R370 rectify the bottom half of 90Hz waveform. The two signals are then summed and filtered by the D-bar driver.

4.3.4.8 D-Bar Driver Detailed Circuit Theory

D-bar current drive for both LOC and VOR is provided by I309A. Input selection is provided by FET switches I310A, C, and D. Gain is determined by feedback resistors R364 and the input resistors. Gain for ILS is adjustable with variable resistor R370. Centering in VOR mode is adjustable with the balance network R365, R367 and variable resistor R366. Capacitors C325 and C326 provide filtering. R363 limits the amount of current the OP AMP can provide to approximately 4ma.

4.3.4.9 Flag Detector and Flag Driver Circuit Theory

The output levels of both bandpass filters are monitored and compared to a reference voltage. Diode CR315 along with C333 peak detect the variable phase bandpass filter output. As long as the voltage at the base of Q306 is greater than the reference voltage on the emitter, the transistor will not conduct. Similarly, Q307 will not conduct if the reference signal level is adequate. If either Q306 or Q307 turn on because of a low level signal, Q308 will turn on. The voltage at J301 pin 9 will then be low, signaling the microprocessor that variable or reference information may be invalid. The microprocessor will send a high signal back on the system flag line. Q303 will turn on causing FET switch I310B to open. The potential on pin 6 of I309B will drop to a level equal to V_{ref} since pin 6 is tied to V_{ref} through R351 and the deviation meter windings. Since pin 5 is at a higher potential than pin 6, the output of I309B will be high (9V) and CR304 will be reverse biased. Diodes CR305 and CR306 will also be reverse biased, since the potential of "ILS HI" is zero. When signal levels are adequate, FET switch I310B will close and the 9 volt line will be the signal applied to the flag amplifier. Gain of the amplifier is determined by the ratio of R351 to R355 and the setting of variable resistor R354.

In the localizer mode, R358 and R359 forward bias CR305, CR306, CR307, and CR308 allowing the signal levels of the 90Hz and 150Hz BPF to control the flag driver. FET switch I310B is in the off state so flag action is analog in nature. Variable resistor R354 is used to set the "flag" level.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

4.3.4.10 ILS Energizer Driver Detailed Circuit Theory

When an ILS frequency is selected by the KNS 81, the ILS line goes to a low logic state. Q304 and Q305 saturate leaving TP310, the "ILS HI" bus, at a logic high. The "ILS LO" bus is at a logic low. These signals are used to operate the various FET and transistor switches within the converter. ILS LO is used as a ground for the glideslope and as an annunciator for indicators or switches external to the KNS 81.

4.3.4.11 9 Volt Regulator Detailed Circuit Theory

Voltage regulation for the converter 9 volt circuitry is provided by I521 (located on the computer board). The four terminal device regulates the 13.5 volts from the power supply down to 9 volts which is filtered by C512. The output level is controlled by R548 and R549.

4.3.5 DISPLAY DETAILED CIRCUIT THEORY

4.3.5.1 Display Timing and Storage

Timing for recirculating new data is provided by a multiplex timer I325. The timer is a 555 operating in an astable mode. R417, R418 and C350 determine the interrupt period. The following things happen when the 555 goes low:

- a. I326, the one-shot that controls the pulse width in the light dimming circuit is reset causing the display to be blanked. (The one-shot will have already been low if the display is operating under dim light conditions). The display is blanked to avoid flickering in the displays as data is shifted serially through the latches.
- b. The anode selection Johnson counter (I317) is incremented one count by the microprocessor. The next set of cathode data will be displayed on the anode selected by the Johnson counter. There are eight possible states of the Johnson counters and eight anodes to display.
- c. The microprocessor (which has been interrupted by I325 going low) outputs the display message in the form of a digital word to the cathode drivers I322, I323 and I327.

After eight periods, all eight anode lines will have been turned on. This completes one multiplex cycle. Approximately 110 of these cycles are completed every second.

4.3.5.2 High Voltage Driver Detailed Circuit Theory

The gas discharge displays need approximately 130 volts between the anode and cathodes to ionize the gas. If a given character is to be lit, the anode above the character is pulled to the +185 volts and the cathode is pulled from 75 volts towards ground until the display "fires". Since the cathode drivers are current sources, the voltage on the cathodes vary depending on the tube characteristics and the current output level. Current levels are "programmed" through pin 1 of drivers I321, I322, I323 and I327. In addition, I321 and I323 are also "current programmed" by a gating network which is operated by the PIA.

4.3.5.3 Dimming Circuitry

The photocell activated dimming circuit adjusts the brightness of the display to compensate for changes in ambient light level. Dimming is accomplished by varying both the duty cycle and current level of the programming current.

Pulse width variation is obtained from a variable duty cycle one-shot I326 which is triggered from the multiplex timer I325. The one-shot's time constant varies 80us to 1100us.

I324B is wired as a constant current source whose output current is used to charge C353, the timing capacitor for the one-shot. The time constant of the one-shot is determined by the magnitude of the current from the current source which, in turn, is controlled by the photocell V300. In darkness, the output current from I324B is at its maximum value of about .75mA, giving the one-shot a time constant of about 80us. As the ambient light level increases, the duty cycle of I326 increases. The maximum time constant is limited by the duty cycle of the multiplex timer, I325. When the output of I325 goes low, it forces the one-shot to reset. Variable resistor R416 controls the minimum time constant of I326 and is used to adjust the minimum display brightness.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

The output of I326 is filtered by R422 and R423 to produce a DC voltage proportional to the duty cycle of the square wave. This DC voltage controls the magnitude of the current from I324A, a constant current source. This current is used as the programming current for the cathode drivers, I321, I322, I323 and I327. Since the drive requirements of a display character differ according to its size, different values of series resistors are used in series with the programming input of the four cathode drivers.

The programming current to the display drivers has a duty cycle that is determined by one-shot I326. Diode CR346 shunts current source I324A to ground when the one-shot is low. By changing both the duty cycle and the level of programming current, approximately 30 to 1 dimming ratios are obtained.

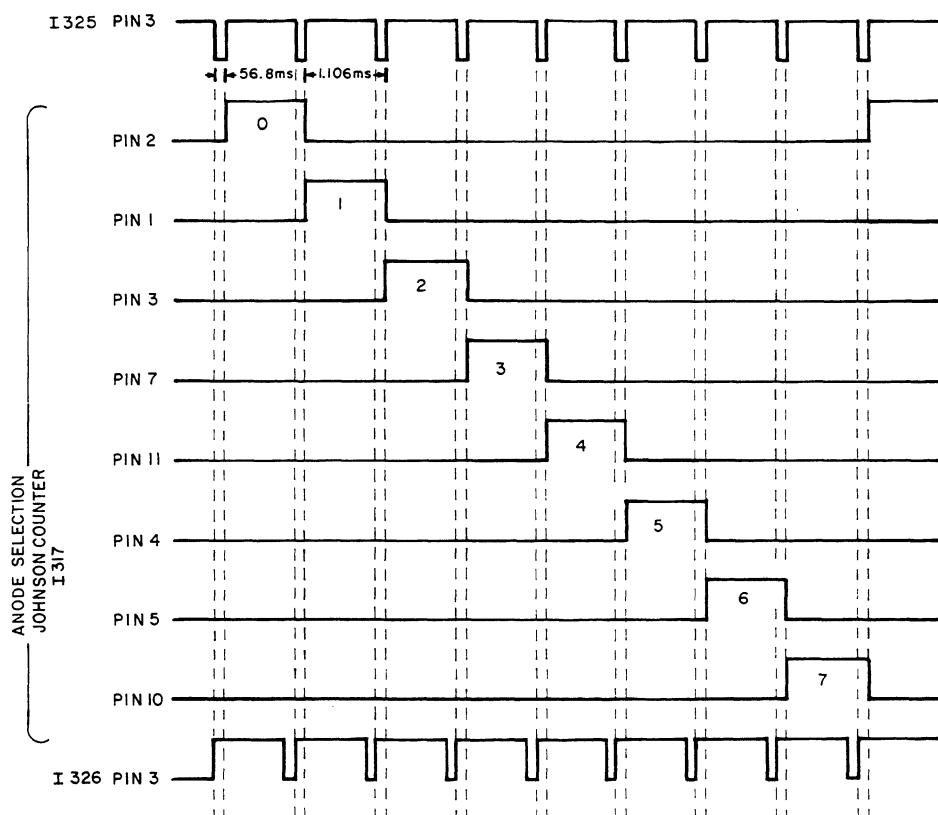

FIGURE 4-14 DISPLAY TIMING DIAGRAM

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

4.3.6 GLIDESLOPE RECEIVER DETAILED CIRCUIT THEORY

4.3.6.1 Preselector

The first stage of the preselector is formed by Q800 and its associated components. Gate 1 of Q800 is tuned by L800 and variable capacitor C801. L801 and C805 provide the tuning for the drain of Q800. The second preselector stage is formed by Q801 and its associated components. Q801's drain is tuned using L802 and C810. Both the first and the second stages are tuned to resonate at approximately 332MHz. The gain of Q800 is 10dB and Q801 has about the same amount giving a total gain of 20dB before reaching the mixer stage. Q800 and Q801 are both dual gate, N channel, enhancement mode, field effect transistors. Since these are enhancement mode devices, their gates must be positive biased for proper operation. The tuning of these stages provides the necessary preselection of the RF signal.

4.3.6.2 Mixer

Capacitor C813 couples the preselector output to the mixer stage (Q802). Q802 is also a dual gate FET with the preselector output applied to Gate 1 and the buffered VCO (local oscillator) signal applied to Gate 2. Gate 1 and Gate 2 are biased by R808 and R811. Q802 mixes the local oscillator signal and the preselector RF signal to produce an IF frequency of 33.33KHz.

4.3.6.3 IF Amplifier and Elliptic IF Filter

The first IF amplifier is formed by Q803 and its associated circuitry and has a gain of 37dB. The output of Q803 is then passed into the elliptic IF filter. This filter consists of a three section low pass filter with three tuned circuits to provide three distinct notches in the frequency response. The elliptic filter has a 6dB break point at approximately 60KHz and 60dB of rejection at 79.5KHz. C830 couples the signal from the elliptic filter to the second IF amplifier, I800. The gain of I800 is controlled by AGC action on pin 5. C835 then couples the output of the second IF amplifier to the third IF amplifier, Q804 and its circuitry. R824 and R825 provide the biasing for Q804. The output of Q804 is coupled to the detector stage through C837.

4.3.6.4 Detector

Q805 and R829 develop the base bias for Q806. The collector of Q805 is shorted to the base so that it will function as a diode with the same thermal characteristics as Q806. On positive swings, Q806 will conduct and on negative swings Q806 will cut off, thus providing detection. R830 and C838 will filter out the IF frequency from the composite audio.

4.3.6.5 IF AGC Amplifier

The DC component of the composite signal is sent to the IF AGC amplifier, I801A. I801A is connected as an integrator which uses C846 as feedback. This circuit produces the automatic gain control (AGC) for the IF stage, I800.

4.3.6.6 RF AGC Amplifier

The output of I801A also drives the RF AGC amplifier I801C. I801C provides additional AGC action for high level RF input signals. R836 sets the RF AGC amplifier to attack at the correct RF input level. Gate 2 of Q800 and Q801 control the preselector gain and are driven by the output of I801C.

4.3.6.7 Course Width Amplifier

I801D is the course width amplifier which uses R846 and R843 to control its gain. R846 is adjusted to provide the correct course width indication by changing the gain of I801D.

4.3.6.8 Glideslope Synthesizer

The local oscillator signal is developed and frequency controlled by a phase locked loop (PLL). The heart of the PLL is the VCO (Q811 and associated components). The VCO is a Colpitts design with L811, CR800, C853, C857 and C858 being the major frequency determining components. The VCO is capable of changing from 164.559MHz to 167.489MHz (RF frequency minus 33.33KHz divided by two) by varying the DC voltage on varactor CR800. The output of the VCO is coupled to the receiver buffer (Q813 and associated components) and the synthesizer buffer (Q814 and associated components). These buffers eliminate frequency pulling of the VCO by the load. The input to the receiver buffer is tuned to the second harmonic of the VCO by series resonant C859 and L808. The output of the receiver buffer is tuned to the second harmonic of the VCO by parallel resonant L806 and the internal capacitance of Q813. This tuning provides frequency doubling in the buffer so that the resultant frequency fed to the mixer is 33.33KHz

below the selected RF frequency. Q812 and associated components provide bias for Q813. The synthesizer buffer provides isolation between the universal synthesizer (I803) and the VCO. The output of the synthesizer buffer drives the prescaler input of the universal synthesizer. The synthesizer receives a 12.8MHz reference input signal from I604 in the NAV receiver. The synthesizer divides the 12.8MHz reference by 1536 to obtain an 8.333KHz reference. The prescaler input is also divided by an integer, referred to as N_T to obtain 8.333KHz. N_T is determined by the serial channeling data on pin 7 of the synthesizer. The synthesizer then phase/frequency compares the divided reference and prescaler inputs. If the frequency of the prescaler is low with respect to the reference, the synthesizer produces "up" pulses on pin 3. If the frequency of the prescaler is high with respect to the reference, the synthesizer produces "down" pulses on pin 2. The "up" and "down" pulses are fed to the charge pump (Q808, Q809, Q810 and associated components). The duty cycle of the "up" or "down" pulses determine the length of time that Q808-Q810 are turned on or off. The length of time that Q808-Q810 are turned on or off determines the average charge on C851. The voltage on C851, in turn tunes CR800, thus determining the VCO frequency. Hence, the loop is completed. C848-C850 and L809 filter the 8.333KHz from the control voltage. L810 provides isolation between the control voltage and the VCO. R838, R839 and C814 provide dither of the VCO. Q815 and associated components turn off I803 when channels other than ILS are selected.

4.3.6.9 90Hz Bandpass Filter

The output of the course width amplifier is applied to R872 and R874. These two resistors determine how much of the detected signal goes to the 90Hz filter or the 150Hz filter. I802D is configured as the 90Hz bandpass filter which uses its associated circuitry to control its gain and to determine the filter's bandwidth.

4.3.6.10 150Hz Bandpass Filter

I802A and its associated components form the 150Hz bandpass filter, which is the same type as the 90Hz filter. The gain and the bandwidth of I802A is controlled by its associated circuitry.

4.3.6.11 Deviation Bar Detectors

CR803 rectifies the 90Hz filter output and passes only the positive portion of the sine wave. This rectified signal charges C871 in the positive direction. The output of the 150Hz bandpass filter is rectified by CR806, which passes only the negative portion of the sine wave. This signal drains the charge from C871, so that the remaining charge on C871 will indicate the difference between the two signals. Noise damping is provided by R879 and R889 and C871.

4.3.6.12 Deviation Bar Driver

I802C is used to drive the deviation indicator (D-bar). The gain of the amplifier is set by R881 and R883, and indicator damping is provided by R883 and C872. I802C is a voltage source, thereby allowing the addition of more than one indicator load without changing the indicators position. CR804, CR805 and R884 provide current limiting to protect the deviation indicators.

4.3.6.13 Flag Peak Detectors

The output of the 90Hz bandpass filter is also rectified by CR802 to provide detection for the flag driver. CR808 rectifies the output of the 150Hz filter. CR801 and CR807 are used to compensate for variations in the voltage across the rectifiers over temperature changes.

4.3.6.14 Flag Driver

I802B and its associated circuitry is used to drive the flag indicator. This driver provides a voltage source so that several flags may be used simultaneously. A summing of the detected 90Hz and 150Hz voltages appears at the input of I802B. Indicator damping is provided by C873 and R891. CR809 and CR810 will limit I802B's output so that it will only drive positive with an amplitude of not greater than 600 millivolts.

4.3.7 COMPUTER DETAILED CIRCUIT THEORY

4.3.7.1 Microprocessor Detailed Circuit Theory

The control lines of the microprocessor are described in this section. Timing in the processor is directed from an internal clock. This internal oscillator is controlled by crystal Y500. The valid memory address (VMA) output indicates to peripheral devices that there is a valid address on the address bus. The Reset input is used to restart the MPU from a power down condition or if the OBI clock stops or also if the Vcc voltage goes below 4.5 volts. The system clock is supplied by the enable pin (E). This output is equivalent to the phase 2 clock of the MC6800 MPU. The read/write (R/W) output signals the peripherals whether the MPU is in a read (high) or write (low) state. The Halt, MR, RE and BA control functions are not used and their control pins are tied to either Vcc or ground, the BA pin is left open.

Non-maskable interrupt (NMI) and interrupt request (IRQ) are hardware interrupt lines which cause the MPU to stop normal sequential program execution and jump to a special section of the program. These interrupt lines are sampled when the clock (E) is high and will start the interrupt routine on a low clock following the completion of an instruction which it was currently working on.

The microprocessor uses the 16 address lines in conjunction with the valid memory address (VMA) to select memory locations in the system. Information is transferred either to or from the processor on the bi-directional data bus depending on the state of the read/write line.

4.3.7.2 Reset Starter Detailed Circuit Theory

For the purpose of condensing the theory of operation and still covering all flavors of the unit, sometimes it will be necessary to show two component designations for a part that serves a common function. When a designation is shown as R537/R540, the R537 applies to the -00 flavor of the computer schematic and assembly drawing and the R540 applies to the -10 flavor of the computer schematic and assembly drawing. When only one component designation is shown it applies to both -00 and -10 assemblies. Refer to the maintenance structure, Table 4-2, to determine what board assembly part numbers and used in different flavors of KNS 81.

When power is first applied to the KNS 81, the microprocessor must be reset to start the initialization program. The power-on clear function is accomplished through C513, R537/R540 and R540/R541. When power is turned on, the capacitor (C513) holds the reset line low. The capacitor charges through R537/R540 and R540/R541 slowly letting the reset line go high. During the charging time, the power to the MPU and the memory is stabilizing so the MPU will operate properly when the reset line goes high.

Comparators I514A/I509A and B/B form a lost program detector. I514B/I509B detects any low pulses on the OBI clock line while I514A/I509A monitors the voltage of a slowly charging capacitor C514/C512. The switching threshold of comparator I514B/I509B is referenced from a resistor divider composed of R546/R532 and R547/R533. The reference for comparator I514A/I509A is supplied by the resistor divider of R543/R537 and R544/R538. Whenever there is a high level on pin 5 of I514B/I509A, the output of the comparator is high impedance state, which allows C514/C512 to charge through R537/R536 and R539/R540. A low pulse on pin 5 of I514B/I509B causes its output to go low and drain some of the charge from C514/C512, thus preventing it from charging up to I514A's/I509A's reference voltage. If there are no low pulses occurring at pin 5 of I514B/I509B, the capacitor C514/C512 will be allowed to charge up to I514A's/I509A's reference level. Once this level is exceeded by C514/C512, the output of I514A/I509A goes low causing the reset line to go low and reset the MPU. When the OBI clock is running normally, there should be enough low pulses occurring to keep C514/C512 from charging to the reference voltage.

I514C/I509C and D/D are the comparators which form a low voltage reset circuit. I514D/I509D monitors the +5 volt line, while I514C/I509C monitors the charge on capacitor C508/C525. This capacitor is used to filter out short pulses which may occur but will not affect the operation of the MPU. The reference voltage for I514D/I509D is supplied by the zener diode I520/I519 and resistor divider R532/R574 and R533/R575. If the 5 volt line ever drops below this reference level, the output of I514D/I509D goes low and begins drawing the charge from C508/C525. When the voltage on the capacitor gets below the reference of I514C/I509C, supplied by resistor divider R530/R572 and R531/R573, the output of I514C/I509C goes low pulling the reset line low and resetting the MPU and associated peripherals. During normal operation, C508/C525 should be charged greater than the reference voltage.

4.3.7.3 Computer Memory Detailed Circuit Theory

For the purpose of condensing the theory of operation and still covering all flavors of the unit, sometimes it will be necessary to show two component designations for a part that serves a common function. When a designation is shown as R537/R540, the R537 applies to the -00 flavor of the computer schematic and assembly drawing and the R540 applies to the -10 flavor of the computer schematic and assembly drawing. When only one component designation is shown it applies to both -00 and -10 assemblies. Refer to the maintenance structure, Table 4-2, to determine what board assembly part numbers and used in different flavors of KNS 81.

I501, I508, I512 and I519/I501, I512, I514, I515 and I521 form the memory for the computer. The MPU itself has 128 bytes of RAM built into it. An individual location is accessed by applying the correct address to the address (A) lines and also having the correct chip select line enabled. Data is returned through the data bus (DB0-DB7). The address lines to the memory are valid when the VMA signal from the microprocessor is high. Data is sent or received depending on the state of the read/write line. Figure 4-15 and Figure 4-16 show timing relationships between various signals.

4.3.7.4 Peripheral Interface Adapter (PIA)

The peripheral interface adapter provides the means of interfacing the microprocessor to external circuitry. The functional configuration of the PIA is determined during system initialization which occurs immediately after the reset. Each of the peripheral data lines is programmed as either an output or an input at this time. Information is sent to or read from the PIA on the data lines, DB0-DB7, when the correct address is applied to the chip selects. Data is transferred to the PIA if the read/write line is low and read from the PIA if the read/write line is high. The enable pin is tied to the enable pin of the MPU so that data transfer takes place when the clock is high. Data written into the PIA is latched at the PIA output ports. No microprocessor updating of the PIA is needed except when the data is to be changed. Figure 4-17 lists the functions of the PIA's.

DIGITAL AREA NAVIGATION SYSTEM

4.3.7.5 D-bar Digital to Analog Converter

For the purpose of condensing the theory of operation and still covering all flavors of the unit, sometimes it will be necessary to show two component designations for a part that serves a common function. When a designation is shown as R537/R540, the R537 applies to the -00 flavor of the computer schematic and assembly drawing and the R540 applies to the -10 flavor of the computer schematic and assembly drawing. When only one component designation is shown it applies to both -00 and -10 assemblies. Refer to the maintenance structure, Table 4-2, to determine what board assembly part numbers and used in different flavors of KNS 81.

Left/right information for the D-bar is converted from a digital word to a DC voltage signal with shift register I522/I516 and resistance ladder network U500/U501. Data is clocked into the shift register serially. Data from the shift register output Q2 produces twice the effect that data from Q1 produces and data from Q3 produces twice as much effect as Q2 and so on. The digital word containing all ones represents maximum left deflection and all zeroes represent maximum right deflection.

4.3.7.6 Increment/Decrement Switch Circuit Theory

(-0X & -18 flavors)

Rotation of the knobs is detected by flip-flops I515, I516 and I517. There are four lines coming from each switch assembly: LL, S TO GIVE A LOGIC HIGH AT PIN 1 (Q1) to indicate the large knob on the right side was moved. A high at pin 13 (Q2) of I516 would indicate the small knob on the right side was moved. I517 is wired the same as I516 so when a high occurs on pin 1 (Q1) it indicates the large knob on the left side was turned. A high on pin 13 (Q2) of I517 would indicate that the small knob on the left side was turned. The microprocessor senses the outputs of the flip flops so that it knows which knob was turned and in which direction it was turned. The microprocessor can now update the display. The microprocessor will reset I516 and I517 after it has read the information from them.

(-1X,-2X,-3X except -18 flavors)

Rotation of the knobs is detected by flip-flop I507 and latches I508. There are four lines coming from each switch assembly: LL, P₁L, P₂L and RL are from the left switches while LR, P₁R, P₂R and RR are from the right switches. I507 will indicate the direction of any knob rotation. I508 will indicate which knob was rotated. I507 is wired such that a clockwise rotation (increment) yields a logic high from the flip-flop and a counter-clockwise rotation (decrement) yields a logic low from the flip-flop. It should be noted that while the pulse from the switch is a positive leading edge on the -00 computer boards and a negative leading edge on the -10 computer boards it makes no difference to the flip-flops since timing is not critical. To determine which knob was rotated, latches (I508) are used instead of flip-flop as on the -00 computer boards.

Again different logic states are produced by the -00 computer board switches and the -10 computer board switches. I508 is wired so a logic high from Pin 4 indicates the large right knob, Pin 7 indicates the small right knob, and Pins 9 and 13 indicate the mode and waypoint knobs respectively. By sensing these outputs the microprocessor knows which knob was turned and in which direction and updates the display accordingly. The microprocessor then resets the flip-flop and latches after reading their information.

4.3.7.7 EAROM Detailed Circuit Theory

For the purpose of condensing the theory of operation and still covering all flavors of the unit, sometimes it will be necessary to show two component designations for a part that serves a common function. When a designation is shown as R537/R540, the R537 applies to the -00 flavor of the computer schematic and assembly drawing and the R540 applies to the -10 flavor of the computer schematic and assembly drawing. When only one component designation is shown it applies to both -00 and -10 assemblies. Refer to the maintenance structure, Table 4-2, to determine what board assembly part numbers and used in different flavors of KNS 81.

The electrically alterable read only memory (I519)/(I521) is used to store waypoint information during the power off condition. The EAROM receives its data and address information through the serial I/O line (pin 12). The three control pins (C1, C2, C3) are used to select the mode of operation for the EAROM. By applying a certain code of ones and zeros, the standby, accept address, read, write, data out, accept data, or erase modes can be selected. When the microprocessor does a write operation to the EAROM, it will output the correct control code to PIA 4 (I512)/(I513). The PIA will then send the code to I518A/I520A, B/B and D/D for a five volt to nine volt level shift. The microprocessor will also output one bit of data and one clock pulse at the same time as the control code. The data is sent through PIA 4 to I518F/I520F, a buffer, and then shifted into the EAROM's address shift register. Once the address is

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

shifted into the EAROM, the data to be stored at the location can be sent out along with the "write" control code. The transistor, Q506/Q510 and resistors R525/R577, R526/R578 and R527/R579 form a pull up circuit for the data input line. When data is to be sent out of the EAROM, control line C2 will be a low. This low is sensed by I518C/I520C and will cause Q506/Q510 to turn on and pull the data input line to nine volts. I518/I520 outputs are all open collector type so no damage to the buffers occurs by the level shifting. The capacitors on the control lines (C524/C528, C525/C529, C526/C530) filter out short spike pulses which may occur on these lines. Figure 4-18 shows some of the timing relationships between various signals.

KNS 81
DIGITAL AREA NAVIGATION SYSTEM

4.3.7.8 DME Interface Detailed Circuit Theory

(-DX & -18 Flavors)

The DME interface is provided so the microprocessor can communicate with an external DME. Data is transferred to and from the microprocessor through a bi-directional serial data bus. When the DME is sending data, it will cause the DME data request line to go high. This signal is inverted through I504 and fed into the reset pins of I511. CR512 is used for protection against over-voltage. The low signal on the reset pins causes all of the Q outputs of I511 to go to a logic low allowing the DME bus clock to go through I505A and B and clock I506 and I507. The DME data request line being high allows I511 to count the number of clock pulses at pin 2. When Q1 (pin 12) of I511 goes high, the 20 bits of data from the DME should now be shifted into I507 and I506. The microprocessor will be interrupted by this high level on PIA 1 (I502) pin 40. The microprocessor will now send out a clock signal on PIA 1 pin 39 to clock out the data contained in I506 and I507. The data will go to the microprocessor through PIA 1 pin 2. After 32 milliseconds, the DME data request line will go low again resetting I511. The computer uses the DME data to compute RNAV or VOR parallel problems.

After the DME request line goes low, the RNAV/Channel request line goes to a high level to interrupt the MPU. The interrupt will cause the microprocessor to send out a 50 bit word if the unit is in the RNAV mode or if the RAD button is pushed. In all other modes, the MPU will send a 10 bit word to the DME. The DME COMMON Line will be a logic low if the KNS 81 is to be used to remote tune the DME. This line is monitored by the MPU so that it will know if it is required to send out tuning data or not. The decoding gates of I505, I524, I504 and I503 control Q500 and the state of the 10 bit/50 bit line. If the DME COMMON Line is low, and if the RAD button is not pushed, the output (pin 11) of I505 will be a high. If the KNS 81 is in the RNAV mode, there will be a high level at the collector of Q503 which is applied to pin 8 of I524C. The output of I524C will then go to a logic high and cause transistor Q500 to turn on, which will drive the 10 bit/50 bit line to be low. This tells the DME to expect a 50 bit word on the data bus. If the KNS 81 is not in the RNAV mode, the output of I524C would be a low. The transistor (Q500) would not turn on so the 10 bit/50 bit line would remain at a high level, telling the DME to expect a 10 bit word on the data bus. If the RAD button is pushed, it will cause the same effect as in the RNAV mode by causing the output of the NAND gate (I505D) to go low.

When the MPU outputs the data for the DME, it will send data to PIA 1 (I502) along with a clock signal. These signals go out of PIA 1 pins 3 and 4 to two NAND gates (I525A and B). If the RNAV/Channel request line is high, I524A's output will be high also. Now the bus clock and DME data out will be allowed through the NAND gates. The DME data out will go from I525A pin 3 through R559 and to the base of Q507 which turns the transistor on or off depending upon the level of the data being sent. The bus clock will do the same to transistor Q508. The DME data out can be seen at TP509 and the bus clock can be seen at TP510. Figure 4-19 shows some of the timing relationships of some of the signals. Figure 4-20 shows the functions of the 50 bit word.

(-1X/-2X/-3X except -18 Flavors)

The DME interface is provided so the microprocessor can communicate with an external DME. Clock and data are transferred to and from the microprocessor through bi-directional serial buses. DME request, clock bus, and data buses are level shifted from +9V to +5V by I518 B, F, and D respectively. When the DME is sending data DME request goes high enabling NAND gate I505D and allowing clock data to pass. CA2 of PIA1 is high allowing clock data to pass a second NAND gate (I505C) to the shift register I504. When DME request transistors low CA1 of PIA1 is also pulled low interrupting the microprocessor which outputs clock pulses through CA2 of PIA1. Because the output of NAND gate I505D is high due to DME request being low, NAND gate I505C is enabled and CA2 will clock the needed data from the shift register into PIA1. Concurrent to DME request going low clock and data information to the DME is output by PIA1. Q501 is constantly held high, enabling NAND gates I500A and B. Clock and data is level shifted from +5V to +9V by Q500 and Q502 and output to the DME. Q501's purpose is to prevent the microprocessor from talking on the bus during power up by keeping NAND gates I500 A and B disabled until the microprocessor power up initialization is complete. Completion is indicated by PB3 of PIA2.

TABLE 4-2 KNS 81 MAINTENANCE STRUCTURE
(Dwg. No. 696-5268-00, R-0)

The KNS 81 is divided into three versions or families: -0X/-1X/-2X and -3X. All versions use the same NAV Receiver, Glideslope Receiver (optional), Power Supply and Switch Board. The flavor differences are created in the Converter/Display Board and the Computer Board. The -1X/-2X/-3X except -18 families use the same Converter/Display Board and Computer Board and are identical except for small flavor differences. For this reason the -1X/-2X/-3X families are referred to as -1X/-2X/-3X. The -0X family however uses a functionally similar but electrically different Computer Board and Converter/Display Board. The following Table should help clarify which schematic and assembly to use with each flavor of KNS 81.

SECTION V MAINTENANCE

5.1 GENERAL INFORMATION

This section contains test, alignment, inspection, cleaning, repair, and troubleshooting procedures for the KNS 81. Included are detailed assembly/disassembly instructions and troubleshooting flowcharts. Schematic diagrams are illustrated in Section 6.0.

Information concerning semiconductor test equipment, semiconductor and integrated circuit maintenance, and specific integrated circuits used in the KNS 81 may be found in Appendix A at the end of this manual. It is suggested that Appendix A be consulted before attempting to service the KNS 81.

5.2 TEST AND ALIGNMENT

5.2.1 GENERAL INFORMATION

The test procedures of Section 5.2.4 may be followed to determine if the KNS 81 is operating properly. If it is not, the alignment procedures are given to bring the KNS 81 up to minimum performance standards.

5.2.2 TEST EQUIPMENT REQUIRED

The following test equipment or equivalent is needed to align and troubleshoot the KNS 81.

- A. Power Supply - 13-28V at 3 amps
- B. Oscilloscope - Tektronix 465
- C. Digital Voltmeter - Fluke 8600A
- D. VOR RF Generator - HP 8640B
- E. VOR/ILS Modulator - TIC-T20A
- F. Attenuators - 6dB pad, 50 ohm
- G. RF VTVM - HP 3400A
- H. Audio VTVM - Ballentine 310A/B
- I. Frequency Counter - Eldorado 1615C
- J. Precision Track Selector - 479V-3
- K. Audio Oscillator - Hewlett Packard 2000CD
- L. DME Test Set - IFR ATC - 1200Y3 or equivalent
- N. KNS 81 Test Panel

5.2.3 ALIGNMENT PROCEDURES

The following procedures describe how to align the KNS 81 once the test procedures have been completed to prove alignment is necessary. A sequential order has been followed for complete alignment. Refer to the schematics and assembly drawings for location of components, test points, and adjustments. The numbering sequence is as follows:

<u>SCHEMATICS</u>	<u>COMPONENT OF TEST POINT DESIGNATORS</u>
Power Supply Board	100 - 199
Switch Board	200 - 299
Converter/Display Board	300 - 499
Computer Board	500 - 599
NAV Receiver Board	600 - 799
Glideslope Board	800 - 899

Unless otherwise stated, alignment should be performed with standard test signals and input conditions as defined in Section 5.2.3.1.

5.2.3.1 Standard Test Signal Description

a. Standard VOR Test Signal

An RF carrier, amplitude modulated simultaneously at $30 \pm 1\%$ by a 9960Hz subcarrier which, in turn is frequency modulated at a deviation ratio of ± 16 by a $30 \pm .1\%$ "Reference Phase Signal" and at $30 \pm 1\%$ by a $30\text{Hz} \pm .1\%$ "Variable Phase Signal" which can be varied in phase with respect to the reference phase signal.

b. Standard Audio Test Signal

An RF carrier amplitude modulated 30% at 1000Hz.

c. Standard Localizer Test Signal

An RF carrier modulated simultaneously with $90\text{Hz} \pm .3\%$ and $150\text{Hz} \pm .3\%$ signal so that the sum of their separate modulation percentages equals $40 \pm 2\%$.

d. Standard Localizer Centering Signal

A standard localizer test signal in which the difference in depth of modulation is less than $.002$ (.1dB).

e. Standard Localizer Deviation Signal

A standard localizer test signal in which the difference in depth of modulation of the 90Hz and 150Hz signal is $.093 \pm .002$ ($4 \pm .1\text{dB}$).

f. Standard Glideslope Test Signal

A $700\mu\text{V}$ RF carrier amplitude modulated simultaneously with 90Hz and 150Hz of such levels that when each signal is applied independently, the carrier is modulated $40 \pm 2\%$.

g. Standard Glideslope Centering Signal

A standard glideslope test signal in which the difference in depth of modulation is less than $.002$.

h. Standard Glideslope Deviation Signal

A standard glideslope test signal in which the difference in depth of modulation of the 90Hz and 150Hz signals is $.091 \pm .002$.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

5.2.3.2 Alignment Conditions

Unless otherwise stated, alignment should be performed with standard test signals as defined in Part II and with the following set of input conditions.

- a. Input Voltage to Power Supply: 13.75V
- b. NAV Channel: 113.00MHz
- c. NAV Signal RF Level: 100uV
- d. KNS 81 Connected To Compatible DME (KN 63 or KDM 706) or TACAN REC. (KTU 709)

5.2.3.3 Power Supply Alignment

- a. Apply 13.75VDC to the power input line of the KNS 81.
- b. Monitor TP518 with a DVM. TP518 is located on the computer board.
- c. The reading at TP518 should be 5.0VDC \pm .05VDC. If the voltage needs adjusting, proceed as follows.
 - d. Remove the power supply cover.
 - e. Adjust R125 for a 5V .05VDC reading at TP518.

5.2.3.4 NAV Receiver and Synthesizer Alignment

- a. Reference Oscillator and VCO Alignment
 - (1) Remove the NAV receiver cover.
 - (2) Tune the KNS 81 to 113.00MHz.
 - (3) Set the signal generator to 113.00MHz at 100uV output.
 - (4) Monitor TP602 with a frequency counter.
 - (5) Adjust C648 for 101.9MHz \pm 100Hz.
 - (6) Monitor TP606 with a DVM.
 - (7) Adjust L612 for 4.5 \pm 0.1VDC.
 - (8) Set the signal generator to a standard modulated signal at 113.05MHz at 1000uV.
 - (9) Monitor TP604 with a DVM.
 - (10) Temporarily attach a 510K ohm resistor to either side of R684 to ground. See Figure 5-4 for tool. Note: The resistor should be clipped in position.
 - (11) Adjust L610 for a minimum voltage.
 - (12) Remove the 510K resistor.
- b. Preselection and IF Alignment
 - (1) Apply a standard audio modulated RF signal at 113.00MHz with a level of 1000uV to the antenna input.
 - (2) Tune the KNS 81 to 113.00MHz.
 - (3) Monitor TP603 with a DVM.

KING

KNS 81
DIGITAL AREA NAVIGATION SYSTEM

- (4) Tune the following for peak voltages. Use the swamping tool as depicted in Figure 5-3 to perform the following adjustments.
 - (a) Swamp L600 by placing the swamping tool across CR600 to ground. See Figure 5-3 for proper placement of tool.
 - (b) Tune L601.
 - (c) Swamp L601 by placing the swamping tool across CR601 to ground. See Figure 5-3 for proper placement of tool.
 - (d) Tune L600.
 - (e) Swamp L603 by placing the swamping tool across CR602 to ground. See Figure 5-3 for proper placement of tool.
 - (f) Tune L604.
 - (g) Swamp L604 by placing the swamping tool across CR603 to ground. See Figure 5-3 for proper placement of tool.
 - (h) Tune L603.
 - (i) With the tool removed, tune the following.
 - (j) Tune T600.
 - (k) Tune T601.
 - (l) Tune T602.
 - (m) Tune T603.
 - (5) Decrease the signal generator level to 10uv and repeat step 4, items a through m.
- c. RF AGC Alignment
- (1) Set the signal generator level to 2uv.
 - (2) Monitor TP604 with a DVM.
 - (3) Adjust R649 for maximum voltage.
 - (4) Readjust to .1V less than maximum voltage.
- d. Ident Filter Alignment
- (1) Apply a 113.00MHz signal of 1000uv modulated 30% by a 1020Hz tone.
 - (2) Set the Ident On/Off switch to the IN position.
 - (3) Monitor the audio out line with a VTVM.
 - (4) Adjust R640 for a minimum RMS voltage.
- e. Composite Out
- (1) Use the 30Hz variable modulation only.
 - (2) Monitor TP605 with a VTVM.
 - (3) Adjust R633 for .35VRMS.

5.2.3.5 Converter/Display Board

The D-bar and flag outputs are expressed in mV rather than uA since the drivers are voltage and not current sources.

- a. Remove the top cover to the converter board.
- b. Set the signal generator to 114.90MHz.
- c. Apply a standard VOR test signal at 1000uV.
- d. Set the KNS 81 to 114.90MHz.
- e. Set the KNS 81 to the VOR mode.
- f. Present a DME signal to the DME input of the KNS 81. Simulated DME signal can be provided from a KTS 143 Digital Test Set.
- g. Perform the following adjustments:
 - (1) Peak the 30Hz variable filter output at TP302 by adjusting R312. TP302 should be monitored with an oscilloscope.
 - (2) Remove modulation from the RF generator.
 - (3) Monitor TP304 with a scope probe.
 - (4) Adjust R318 for a frequency of $9960 \pm 30\text{Hz}$ at TP304.
 - (5) Replace the modulation.
 - (6) Monitor TP306 with a scope probe.
 - (7) Adjust R409 for a $4.80\text{V p-p} \pm .1\text{V}$ signal.
 - (8) Adjust R331 to peak the 30Hz reference filter at TP306.
 - (9) Monitor both TP302 and TP306 with a scope probe.
 - (10) Adjust R303 so that the amplitudes of the signals at TP302 and TP306 are equal to within 0.2V peak to peak. If the amplitude of the signal at TP306 is less than 4.5 volts peak to peak, adjust R303 for 4.5 volts at TP302.
 - (11) Set the variable PLL VCO voltage at TP314 to $4.6\text{V} \pm .2\text{V}$ by adjusting R442. Signal at TP303 must be $30\text{Hz} \pm .3\text{Hz}$ for this adjustment.
 - (12) With generator set at zero degrees T0, align the two square waves rising edges at TP303 and TP307 to within $.1^\circ$ by adjusting R312.
 - (13) With a standard VOR signal on channel and the KNS 81 in the RNAV mode, remove the DME RF signal. The KNS 81 should then be in a flagged condition.
 - (14) Zero the D-bar to within 1mV with R366.
 - (15) Replace the DME RF signal. The KNS 81 should now be in a non-flagged condition.
 - (16) Set the KNS 81 to the VOR mode.
 - (17) Monitor TP312 with a scope probe.
 - (18) Adjust R349 to set the VCO voltage of the 30Hz PLL to $4.6 \pm .2$ volts. The 30Hz signal input must be accurate to within $.3\text{Hz}$ for this adjustment.
 - (19) Monitor TP303 and TP307 with scope probes.
 - (20) Set the NAV signal generator to 0 degrees "T0".

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

- (21) Adjust R331 to align the two square waves to within $\pm 10\mu s$.
- (22) Set the NAV signal generator to 90 degrees "T0".
- (23) Set the precision track selector to 90 degrees.
- (24) Monitor the D-bar output at L309 and L311 with a DVM. L309 is monitored relative to L311 with the DVM.
- (25) Allow a two (2) minute settling time before any adjustments are made.

NOTE

Grounding of pin 7 of J503 on the computer board will reduce this time to 15 seconds.

- (26) Adjust R342 for $0 \pm 2mV$ between L309 and L311.
 - (27) Set the NAV signal generator to 0 degrees "T0" and the precision track selector to 0 degrees.
 - (28) Again allow for the settling time.
 - (29) Adjust R338 for $0 \pm 2mV$.
 - (30) Repeat steps 21 through 26 until the required null voltage exists at both 0 and 90 degrees with no further adjustments.
 - (31) Apply a standard localizer test signal at 1000uV.
 - (32) Set the signal generator to 110.10MHz.
 - (33) Set the KNS 81 to 110.10MHz.
 - (34) Monitor TP302 with a scope probe.
 - (35) Peak the 90Hz bandpass filter with R308.
 - (36) Monitor TP306 with a scope probe.
 - (37) Peak the 150Hz bandpass filter with R326.
 - (38) Monitor the D-bar outputs at L309 and L311 with a DVM. L309 relative to L311.
 - (39) Adjust R329 to zero the D-bar to within 1mV.
 - (40) Set the NAV generator tone ratio to .093dBm (4dB).
 - (41) Monitor the D-bar outputs L309 and L311.
 - (42) Adjust R370 for $90 \pm 2mV$ of the D-bar deflection.
 - (43) By alternately removing the 90Hz and 150Hz tones, find which one gives the larger flag voltage.
 - (44) Adjust R354 to $125 \pm 5mV$.
- h. Place opaque tape over the photocell.
- (1) Monitor TP311 with a scope probe.
 - (2) Adjust R416 for a pulse width of $110\mu s$.
 - (3) Monitor TP313 with a DVM.
 - (4) Adjust R434 for $185 \pm 1VDC$.

5.2.3.6 Glideslope Board Alignment Procedure

a. Dither

- (1) Disconnect R898 for glideslope alignment.

b. VCO

Under this section you will find two different alignment procedures for the VCO. Alignment 1 requires the use of a spectrum analyzer. Alignment 2 is an acceptable alternate, but not as accurate as Alignment 1.

Alignment 1 (preferred method)

- (1) Tune the KNS 81 to 109.30MHz and the signal generator to 332.00MHz using a standard glideslope signal.
- (2) Connect a frequency counter to E817 and verify that the incoming frequency is 12.8MHz \pm 15Hz. NOTE: If the frequency is not 12.8MHz \pm 15Hz, repeat steps a of the NAV Receiver Alignment and then step 2 of this section.
- (3) Screw L809 core partially out of the can (approximately 3 threads).
- (4) Temporarily attach a 510K ohm resistor from TP806 to ground.
- (5) Connect a spectrum analyzer to TP807.
- (6) Tune the analyzer to 332MHz and observe 8.333KHz sidebands.
- (7) Adjust L809 for minimum sideband.
- (8) Remove the 510K ohm resistor.
- (9) Monitor TP806 with a DVM.
- (10) Adjust L811 for 4.5 \pm 0.1VDC.

Alignment 2 (acceptable alternate)

- (1) Tune the KNS 81 to 109.30MHz and the signal generator to 332.00MHz using a standard glideslope signal.
- (2) Connect a frequency counter to E817 and verify that the incoming frequency is 12.8MHz \pm 15Hz. NOTE: If the frequency is not 12.8MHz \pm 15Hz, repeat step a of the NAV Receiver Alignment and then step 2 of this section.
- (3) Screw L809 core partially out of the can (approximately 3 threads).
- (4) Temporarily attach a 510K ohm resistor from TP806 to ground.
- (5) Tune the signal generator to 331.966MHz at 70uv.
- (6) Connect a DVM to TP802.
- (7) Vary the signal generator frequency slightly until the DVM indication is dipped.
- (8) Adjust L809 for minimum voltage.
- (9) Remove the 510K resistor.
- (10) Monitor TP806 with a DVM.
- (11) Adjust L811 for 4.5 \pm 0.1VDC.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

c. Preselector Adjustment

- (1) Tune KNS 81 to 109.3 and a standard glideslope signal of 332.00MHz.
- (2) Monitor TP804 with a DVM (DCV). Tune the receiver to an indicated frequency of 109.3MHz. Set the signal generator to 332.0MHz at 1000uv with a standard glideslope signal. Adjust C801, L801 and L802 for a minimum DC voltage at TP804.

d. Elliptic Low Pass Filter Alignment

- (1) Remove the RF input.
- (2) Adjust a sine wave signal generator for 162KHz as measured with a frequency counter. Connect the signal generator to TP801.
- (3) Connect a DVM to TP802.
- (4) Observe the no signal voltage at TP802. Adjust the signal generator signal level for .1V above the no signal voltage at TP802.
- (5) Adjust L803 for minimum voltage at TP802.
- (6) Set the signal generator for 83.6KHz as measured with a frequency counter.
- (7) Repeat step 4.
- (8) Adjust L804 for minimum voltage at TP802.
- (9) Set the signal generator for 97.7KHz as measured with a frequency counter.
- (10) Repeat step 4.
- (11) Adjust L805 for minimum voltage at TP802.
- (12) Repeat all of step d for accuracy.

e. RF AGC Attack Adjust

- (1) Monitor TP804 (RF AGC) with a DVM (DCV).
- (2) Set the signal generator output to 30uv.
- (3) Adjust R836 until the voltage on TP804 just begins to drop (.3V drop maximum).

f. Centering Adjust

- (1) Set the signal generator for a standard glideslope centering signal (.000ddm).
- (2) Adjust R873 for $0 \pm 1\text{mv}$ deflection.

g. Course Width Adjust

- (1) Set the signal generator for a standard glideslope deviation signal (.091ddm).
- (2) Adjust R846 for a deflection of $78 \pm 2\text{mv}$. Check both up and down.
- (3) Repeat Steps 6 and 7 as necessary.

h. Reconnect R898.

KNS 81
DIGITAL AREA NAVIGATION SYSTEM

5.2.4 TEST PROCEDURES

5.2.4.1 Conditions for Testing

All specifications pertain to the following set of input and environmental conditions unless otherwise noted.

- a. Ambient room temperature and humidity
- b. Supply Voltage: $13.75 \pm .1$ VDC
- c. Currents stated are currents which would flow through a single standard load unless otherwise stated. The output should be able to produce this current for any number of loads which the KNS 81 was designed for. Standard Loads and the number of loads allowed on the outputs are listed below:

Course Deviation Loads:	0 to 5, 1K Loads
VOR/LOC/RNAV Flag Loads:	0 to 5, 1K Loads
TO/FROM Loads:	0 to 3, 200 Ohm Loads
Glideslope Deviation:	0 to 3, 1K Loads
Glideslope Flag Loads:	0 to 3, 1K Loads
- d. All RF signal voltages in this document are expressed in hard microvolts.
- e. All tests are to be performed with the cover on.
- f. Tests marked with an asterisk are to be performed at the option of quality control.

5.2.4.2 VOR Tests

5.2.4.2.1 Standard Test Signals

a. Standard VOR Test Signal

An RF carrier (114.90MHz) amplitude modulated simultaneously:

- (1) $30 \pm 1\%$ by a 9960Hz subcarrier which is in turn frequency modulated at a deviation ratio of 16 ± 1 by a 30 ± 1 Hz "reference phase signal" and
- (2) $30 \pm 1\%$ by a 30 ± 1 Hz "variable phase signal" which can be varied in phase with respect to the reference phase signal.

b. Standard Audio Test Signal

An RF carrier amplitude modulated 30% at 1000Hz.

c. Standard TACAN test signal

A synthesized VOR Composite

5.2.4.2.2 VOR Test Procedures

Using the test setup of Figure 5-1, the conditions of 5.2.4.1, and the signals of 5.2.4.2.1, check the following parameters:

a. RF Sensitivity

S + N/N 0.2 dBV = ~ 101 dBm (dBm min.)	Solid Flag (S25 + 75, ~ 50 mV)
Freq. 108.00	_____

- c. Deflection Sensitivity - With an RF signal of 100uV, the D-bar deviation current shall be $150 \pm 10\mu\text{A}$ when the phase difference between the two components of a standard VOR test signal differs 10° from the selected course.

Deflection Sensitivity
 RF Signal 100uV D-Bar Current $+10^\circ$ _____ (114.90MHz)
 -67dBm -10° _____ ($150 \pm 10\mu\text{A}$)

- d. Deflection Response - When the difference in phase between the two components of an on course 1000uV standard test signal is changed abruptly, the deflection current should reach 70% of its ultimate value within $3.2 \pm .3$ seconds.

- e. Deflection Linearity - The deflection current shall be within $5\mu\text{A}$ of being proportional to the difference in phase between the two components of the standard VOR test signal. This requirement shall be met at all deflection currents between $\pm 150\mu\text{A}$.

Deflection Linearity (114.90MHz)
 Deflection is monotonic between -10° and $+10^\circ$ _____ ()

- f. Flag Sensitivity - The unit shall not be flagged with an RF input of 2uV or greater.

- g. TO/FROM Flag - The TO/FROM flag current shall be 200uA to 800uA for both the TO and FROM status.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

h. Audio Sensitivity - On any channel, the (S + N)/N ratio as measured at the audio output shall be at least 6dB for an RF input of 2uV or greater.

i. AGC - The audio output produced by a standard audio test signal shall not vary more than 3dB when the RF signal level is changed from 5 to 20,000uV.

AGC 12.50MHz _____ dB (3dB Max.)

j. Birdies - The equivalent carrier level as measured on the IF AGC line shall be less than 0.5uV on all channels.

Spurious Responses 112.50MHz - Image at 112.903MHz
_____ dB (6dB Min.)

k. NAV Audio Output - A 20uV standard audio test signal shall produce at least 50mw (5.0VRMS) into 500 ohms. The volume control shall be capable of reducing the audio to under 5uw (0.05VRMS).

NAV Audio Output _____ VRMS (5.0VRMS Min.) (112.50MHz)

Minimum NAV Audio Output _____ VRMS (.05VRMS Max.)
Volume Control Fully CCW

l. Audio Muting (TACAN Version only)

Audio Output _____ mVRMS (71mVRMS Max.)

m. Audio Frequency Response - With a 100uV RF signal amplitude modulated 30%, the audio output shall not change more than 6dB when the frequency of modulation is varied from 350Hz to 2500Hz.

Audio Frequency Response - 1.KHz Ref. _____ dB.
350Hz _____ dB. (6dB Max.)
2500Hz _____ dB. (6dB Max.)

n. Voice/Ident - With a 100uV RF input modulated 30% with 1020Hz, the voice/ident filter shall attenuate the audio at least 15dB.

Voice/Ident _____ dB (15dB Min.) (112.50MHz)

Audio Distortion _____ % (15% Max.) (112.50MHz)

Cross Modulation - Change in centering error with 30uV desired signal, 10,000uV undesired. _____ uV.

o. VOR Flag Characteristics (114.90MHz)

(1) No RF signal present _____ (0 + 1mV)

(2) Standard VOR signal with 30Hz modulation absent _____ (0 + 1mV)

(3) Standard VOR signal with 9960Hz modulation absent _____ (0 + 1mV)

(4) Standard VOR test signal _____ (325 + 75, -50mV)

p. TACAN (TACAN version only)

TACAN channel 70X (with no RF applied to antenna)

q. VOR Composite Output Level - 0.5 + 0.1VRMS.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

5.2.4.3 Localizer Tests

5.2.4.3.1 Standard Test Signals

- a. Standard Localizer Test Signal - An RF carrier (110.10MHz) modulated simultaneously with 90Hz $\pm .3\%$ and 150Hz $\pm .3\%$ signals so that the sum of their separate modulation percentages equals $40 \pm 2\%$.
- b. Standard Localizer Centering Signal - A standard localizer test signal in which the difference in depth of modulation is less than .002 (.1dB).
- c. Standard Localizer Deviation Signal - A standard localizer test signal in which the difference in depth of modulation of the 90Hz and 150Hz signal is $.093 \pm .002$ ($4 \pm .1$ dB).

5.2.4.3.2 Test Procedures

Using the test setup of Figure 5-1, the conditions of 5.2.4.1, and the signals of 5.2.4.3.1, check the following parameters:

- a. Sensitivity - With a standard localizer test signal, the flag sensitivity shall be no greater than 2uV for 1/2 flag (190uA flag current).

Flag Sensitivity (110.10MHz)

Flag current equals 190uA at _____ uV (2uV Max. = -101dBm)

- b. Centering - With a standard localizer centering RF signal applied at any level between 10uV to 20mV, the D-bar output current shall be 0 ± 5 uA.

D-Bar centering current (110.10MHz)

Centering current 10uV	(+5.0uA)	20mV	(+5.0uA)
-87dBm		-21dBm	

- c. Deflection - When the ddm of a standard localizer test signal is abruptly changed from zero to any value less than ± 0.155 ddm, the output current shall reach 63% of its ultimate value in $6 \pm .2$ seconds.

Deflection Characteristics (110.10MHz)

+.093ddm	-.093ddm
-87dBm 10uV	uA (90 \pm 4.5uA)
-47dBm 1000uV	uA (90 \pm 4.5uA)
-27dBm 10,000uV	uA (90 \pm 4.5uA)

- d. Flag Signal - The flag current shall be less than 130uA if the RF signal is absent (130uA maximum), or if either or both of the 90Hz and 150Hz modulations is absent from an otherwise standard localizer.

Current Characteristics (110.10MHz)

No RF signal	uA (0 \pm 1uA)
-93dBm 5uV standard signal	uA (325 \pm 50uA)
90Hz absent	uA (130uA Max. at -67dBm)
150Hz absent	uA (130uA Max. at -57dBm)

5.2.4.4 Glideslope Tests

5.2.4.4.1 Standard Test Signals

- a. Standard Glideslope Test Signal - A 700uV RF carrier amplitude modulated simultaneously with 90Hz and 150Hz of such levels that when each signal is applied independently, the carrier is modulated $40 \pm 2\%$.
- b. Standard Glideslope Centering Signal - A standard glideslope test signal in which the difference in depth of modulation is less than .002.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

- c. Standard Glideslope Deviation Signal - A standard glideslope test signal in which the difference in depth of modulation of the 90Hz and 150Hz signals is $.091 \pm .002$.
- d. Sensitivity - With a standard glideslope deviation signal applied, the sensitivity shall be no greater than 16uV for at least 60% of standard deflection (47uA deflection current).

Sensitivity - 329.150MHz (108.95) _____ uV (16uV Max. -83dBm)
 332.000MHz (109.30) _____ uV (16uV Max. -83dBm)
 335.000MHz (110.30) _____ uV (16uV Max. -83dBm)

- e. Centering - The deviation current shall be $0 \pm 10\mu A$ when the RF level of a standard glideslope centering signal is varied from 100uV to 10mV.

Centering	-67dBm 100uV ($0 \pm 10\mu A$)	-27dBm 10,000uV ($0 \pm 10\mu A$)
	_____	_____
329.150MHz (108.95)	_____ μA	_____ μA
332.000MHz (109.30)	_____ μA	_____ μA
335.000MHz (110.30)	_____ μA	_____ μA

- f. Selectivity - At a 20uV input signal level, monitor the G/S test output (IF AGC) and use as a reference. The 6dB bandwidth shall not be less than $\pm 25\text{kHz}$. The 40dB bandwidth shall not be greater than $\pm 125\text{kHz}$.

Upper 6dB Freq. >332.025 (Min.) Upper 40dB Freq. <332.125 (Max.)
 Lower 6dB Freq. <331.975 (Max.) Lower 40dB Freq. >331.875 (Min.)

- g. Deflection - The deflection needle of an indicator properly connected to a glideslope receiver shall deflect up when 150Hz is predominant and down when 90Hz is predominant.

The deviation current shall be $78 \pm 12\mu A$ when the level of a standard glideslope deviation is varied from 100uV to 10mV.

Deflection	332MHz + .092ddm	-092ddm $\pm 5\%$
	_____ mV	_____ mV (78 $\pm 3.9\text{mV}$)
-67dBm 100uV	_____ mV	_____ mV (78 $\pm 3.9\text{mV}$)
-47dBm 1000uV	_____ mV	_____ mV (78 $\pm 3.9\text{mV}$)
-27dBm 10,000uV	_____ mV	_____ mV (78 $\pm 3.9\text{mV}$)

- h. Flag Signal - The flag current shall be less than $125\mu A$ if the RF signal is absent or if either or both of the 90Hz and 150Hz modulations is absent from an otherwise standard glideslope signal.

The flag current shall be $325 \pm 65\mu A$ when a standard glideslope test signal is applied at levels from 50uV to 10mV.

As the ddm is increased from 0.175 to 0.8, the deviation current shall not decrease.

Flag Current	RF signal absent	uA ($0 \pm 125\mu A$)
-50dBm (700uV)	90Hz absent	uA ($125\mu A$ Max.)
-50dBm (700uV)	150Hz absent	uA ($125\mu A$ Max.)
-50dBm (700uA)	standard signal	uA ($325 \pm 65\mu A$)

5.2.4.5 Computer Tests

Using the test setup of Figure 5-1 and the conditions of 5.2.4.1, check the following parameters:

Groundspeed Characteristics:

- a. 90% of final value.

- (1) RNAV Mode: 200 seconds
- (2) Initialization short time constant: 47 seconds.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

- b. Groundspeed Freezes - Groundspeed freezes occur during and 15 seconds after:
 - (1) TO/FROM flag change
 - (2) Window dashes (flagged distance to station)
 - (3) USE button pushed
 - (4) Changing the in use information
 - (5) A 45° change in VOR angle in 36 seconds within 15NM of the DME/VOR station
 - (6) VOR to RNAV mode change
- c. Short Time Constant - The KNS 81 goes into a short time constant mode after the groundspeed becomes unfrozen under the following conditions:

<u>Situation</u>	<u>Time In Short Time Constant Mode</u>
1) Window Dashes	60 Seconds
2) A 45° change in VOR angle in 36 seconds.	165 Seconds

Groundspeed accuracy shall be within 2NM at 300NM.

- d. VOR Angle Filter:
 - (1) 2.4 seconds for 63% of full D-bar displacement
- e. Selected Course Filters:
 - (1) 0.8 seconds for 63% of full D-bar displacement
 - (2) There is no computer filtering of selected course for 4 seconds after a 5.6° change is made in the selected course.
- f. RNAV Accuracy - The cross track and along track error shall be less than 02.NM>

5.2.4.6 Display Tests

All segments of the display shall function under both bright and dim conditions. All segments shall appear to be the same brightness and each character should be solidly illuminated.

5.3 OVERHAUL

5.3.1 GENERAL INFORMATION

Overhaul information contained in this section includes inspection procedures, cleaning, repairing and disassembly/assembly procedures for the KNS 81.

5.3.2 VISUAL INSPECTION

This section contains instructions to assist in determining, by inspection, the condition of the KNS 81 assemblies. Defects resulting from wear, physical damage, deterioration, or other causes can be found by these inspection procedures. To aid inspection, detailed procedures are arranged in alphabetical order.

A. Capacitors, Fixed

Inspect capacitors for case damage, body damage, and cracked, broken, or charred insulation. Check for loose, broken, or corroded terminal studs, lugs or leads. Inspect for loose, broken, or improperly soldered connections.

B. Capacitors, Variable

Inspect trimmers for chipped and cracked bodies, damaged dielectrics and damaged contacts.

C. Chassis

Inspect the chassis for deformation, dents, punctures, badly worn surfaces, damaged connectors, damaged fastener devices, component corrosion, and damage to the finish.

D. Connectors

Inspect connectors for broken parts, deformed shells or clamps, and other irregularities. Inspect for cracked or broken insulation and for contacts that are broken, deformed, or out of alignment. Also, check for corroded or damaged plating on contacts and for loose, improperly soldered, broken, or corroded terminal connections.

E. Covers and Shields

Inspect covers and shields for punctures, deep dents, and badly worn surfaces. Also, check for corrosion and damage to finish.

F. Insulators

Inspect insulators for evidence of damage such as broken or chipped edges, burned areas, and presence of foreign matter.

G. Jacks

Inspect all jacks for corrosion, rust, loose or broken parts, cracked insulation, bad contacts, or other irregularities.

H. Potentiometers

Inspect all potentiometers for evidence of damage such as dents, cracked insulation or other irregularities.

I. Resistors, Fixed

Inspect the fixed resistors for cracked, broken, blistered, or charred bodies and loose, broken, or improperly soldered or corroded terminal connections.

J. RF Coils

Inspect all RF coils for broken leads, loose mountings, and loose, improperly soldered, or broken terminal connections. Check for crushed, scratched, cut or charred windings. Inspect the windings, leads, terminals and connections for corrosion or physical damage. Check for physical damage to forms and tuning slug adjustment screws.

KING

KNS 81
DIGITAL AREA NAVIGATION SYSTEM

K. Transformers

1. Inspect for signs of excessive heating, physical damage to case, cracked or broken insulation, and other abnormal conditions.
2. Inspect for corroded, poorly soldered, or loose connecting wires.

L. Wiring

Inspect wiring for breaks in insulation, conductor breaks, and improper dress in relation to adjacent wiring or chassis.

5.3.3 CLEANING

- A. Using a clean, lint-free cloth lightly moistened with a regular cleaning detergent, remove the foreign matter from the equipment case and unit front panels. Wipe dry using a clean, dry, lint-free cloth.
- B. Using a hand controlled dry air jet (not more than 15psi), blow the dust from inaccessible areas. Care should be taken to prevent damage by the air blast.
- C. Clean the receptacles and plugs with a hand controlled dry air jet (not more than 25psi), and a clean, lint-free cloth lightly moistened with an approved cleaning solvent. Wipe dry with a clean, dry, lint-free cloth.

5.3.3.1 Repair

This section describes the procedure, along with any special techniques for replacing damaged or defective components of the KNS 81.

A. Diodes

Diodes used in the KNS 81 are silicon and germanium. Use long nose pliers as a heatsink under normal soldering conditions. Note the diode polarity before removal.

B. Integrated Circuits

The large scale integrated circuits (LSI's) used in the KNS 81 are mounted in sockets for easy replacement. Use the insert/extract tool included in the LSI Insertion/Extraction Kit (KPN 050-1671-00) for removing or replacing the LSI's. Refer to the instructions included in the kit. Be careful to avoid breaking the IC package during removal and insertion. Carefully line up the pins of the IC with the holes in the socket when replacing it. Be sure pin 1 (marked with a dot on the case or slot in the pin) is oriented properly. The medium scale integrated circuits are soldered to the PC boards. Refer to the integrated circuit maintenance section in the Appendix for removal and replacement instructions. The LSI's and CMOS integrated circuits may be damaged by static electricity and should be kept in conductive packaging when not installed.

C. PC Boards

Use a low wattage soldering iron to avoid damaging the boards by excessive heat. A path that has opened up on the top or bottom of a board can be replaced with insulated hookup wire.

D. Transistors

Refer to semiconductor maintenance section in the Appendix for removal and replacement instructions.

5.3.4 DISASSEMBLY/ASSEMBLY PROCEDURES

The KNS 81 assembly drawings are located in Figures 6-1, 6-2, 6-3 and 6-4. The unit is constructed so that it can be unfolded allowing access to most of the components. Connections between the glideslope (optional) and NAV receiver to the computer board are made by flexible ribbon cables. The connection between the glideslope and NAV receiver is made by a single coax cable. If access to only one section is needed, refer to the appropriate disassembly section. Assembly may be accomplished by following the steps in reverse order referring to the appropriate assembly drawings when necessary. (Figures 6-1, 6-2, 6-3 and 6-4.)

5.3.4.1 Converter/Display Board Access and Removal

The converter/display board is the top board of the unit. For access only for testing, remove the top cover plate. There are two screws on each side, two screws on the rear and one screw on top of the unit towards the center front. Removal of these seven screws will permit the top cover to be removed to expose the component side of converter/display board. For access to the bottom side of board for parts replacement, it is recommended to remove the computer board from the unit. Follow the instructions in the Computer Board Access and Removal section.

5.3.4.2 Computer Board Access and Removal

For access to the computer board, the unit must be unfolded. The arrow marked screws will allow the unit to be unfolded. For access to the bottom side of the computer board and/or converter/display board, follow the instructions below in the order given. For assembly, follow the instructions below in reverse order:

- a. Remove the top cover.
- b. Remove the faceplate by removing two screws on each side and one screw on the bottom of the faceplate. The faceplate will pull forward. Gently push up on the display on the bottom corners for removal. When replacing the display, insert the display at an angle into the connector pins. (Make sure contacts and connectors are aligned). Gently push back and down on the top corners of display.
- c. With the top cover removed, remove the screw on the converter/display panel located near the center rear of the board. This screw is between the row of ferrite beads.
- d. Remove the screw which holds down the power supply case tab in the center of the converter/display board.
- e. Remove the five arrow marked screws and unfold the unit. These screws are located two on each side and one on the rear.
- f. Disconnect the ribbon connectors from the computer board.
- g. Remove two screws, one on each corner of the switch board.
- h. Remove the five screws along the edge of the computer board which connect the computer board to the case.
- i. The computer board can now be gently lifted out and apart from the converter/display board. Care must be taken when disconnecting or connecting the interconnects between the computer board and converter/display board so as not to bend the connectors or damage the PC pads.

5.3.4.3 NAV Receiver Board/Glideslope Board Access and Removal

Remove the six arrow marked screws on the side, back, and bottom of the unit and unfold. Disconnect the ribbon connectors from the computer board. Removal of the top cover plates of the NAV receiver or the glideslope will permit access for testing. Removal of either board for parts replacement is done by removing the four screws from underneath the NAV receiver on the bottom of unit, or the five screws from the top side of the glideslope board.

KING

KNS 81
DIGITAL AREA NAVIGATION SYSTEM

5.3.4.4 Power Supply Board Access and Removal

The unit does not have to be unfolded if only the power supply is to be tested. Remove the top cover plate of the unit. Two screws on each side, two screws in the rear, and one screw on the top of the unit towards the center front will remove the top cover plate. Remove the four corner screws of the power supply cover and lift. This will permit access for testing. To remove the power supply board from the unit, the entire case must be removed from the unit. Follow the instructions below in the order given. For assembly, follow the instructions below in reverse order.

- a. Remove the top cover of the unit.
- b. Remove the screw in the center of the converter/display board which holds down the power supply tab.
- c. Remove the two screws on the side of the unit which holds the power supply to the case.
- d. Unplug the wires from the converter/display board and the entire power supply case can be removed from the unit.
- e. Remove the cover.
- f. Remove the two screws on the heat sinks of the transistors on the side of the case. (When replacing the screws, make sure the transistor tabs are not shorted to the side of the case. Check for shorts with an ohm meter.)
- g. Unscrew the four standoffs, one in each corner, and the power supply board can be removed.

ILLUSTRATED PARTS LIST

INTRODUCTION

This Illustrated Parts List (IPL) provides for the proper identification of replacement parts. Individual Bills of Material (BOM) within this IPL are arranged in numerical order by BOM number. Each BOM is followed by the Assembly Drawing and Schematic Diagram for that assembly.

Parts identified in this IPL by King Part Number meet design specifications for this equipment and are the recommended replacement parts. Warranty information concerning King replacement parts are contained in Service Memo #1, KPN 800-8001-XX.

BILL OF MATERIAL DESCRIPTION

This section describes the various items that appear on the Bills of Material. A sample BOM is included in this section as Figure 6-1.

1. BOM Number

The Bill of Material Number appears at the top of the BOM as a 9-digit number which is also the King Part Number for the assembly. The BOM Number is followed by the assembly description and the revision level of the BOM.

2. Symbol Column

This column contains the Reference Designators of the electrical components of the assembly. Mechanical parts are not assigned Reference Designators. The Reference Designator consists of a letter abbreviation which indicates the type of component followed by the number assigned to that part (C101, Q101, etc). Common Reference Designator abbreviations are listed below.

C	Capacitor	P	Plug
CJ	Circuit Jumper	R	Resistor
CR	Diode	S	Switch
DS	Lamp	T	Transformer
F	Fuse	TP	Test Point
FL	Filter	U	Resistor/Capacitor Network
I	Integrated Circuit	V	Photocell/Vacuum Tube
J	Jack	WG	Waveguide
L	Inductor	Y	Crystal
Q	Transistor		

3. Part Number Column

This column contains the King Part Number for each part. Special purpose 999-9999-XX series part numbers may appear in the BOM and are described below.

1. CR401 999-9999-96 RESERVED

The Reference Designator CR 401 has been reserved for future use; the assembly does not currently include a CR401.

2. CR401 999-9999-97 SEE NEXT ASSEMBLY

CR401 is a part of the electrical circuit but due to assembly or testing requirements is actually part of a different assembly.

3. CR401 999-9999-98 NOT USED

The Reference Designator CR401 is available for future assignment. The assembly does not currently include a CR 401.

KING
KNS 81
DIGITAL AREA NAVIGATION SYSTEM

4. CR401 999-9999-99 DO NOT USE

The Reference Designator CR401 has been previously used for this assembly and later deleted. It may not be reassigned on this assembly.

4. Description Column

This column contains the description of each part in the assembly. Common abbreviations which may appear in this column are listed below.

AL	Aluminum	PC	Polycarbonate
BIFLR	Bifilar	PF	Precision Film
BOM	Bill of Material	PP	Paper
CC	Carbon Composite	PS	Polystrene
CF	Carbon Film	QW	Quarter Watt
CH	Choke	RES	Resistor
CAP	Capacitor	S	Silicon
CR	Ceramic	SCR	Screw
DC	Disc Ceramic	SM	Silver Mica
DIO	Diode	STDF	Standoff
EL	Electrolytic	SW	Switch
FC	Fixed Composition	TERM	Terminal
FERR	Ferrite	TN	Tantalum
FLTR	Filter	TST PT	Test Point
FT	Feedthru	TW	Tenth Watt
HV	High Voltage	VA	Variable
HW	Half Watt	WW	Wire Wound
IC	Integrated Circuit	XFMR	Transformer
MC	Monolithic Ceramic	XSTR	Transistor
MY	Mylar	XTAL	Crystal

5. Assembly (A) Column

An "A" in this column indicates that the part indicated is an assembly. If the KPN and description reads "200-XXXX-99 COMMON BOM" the parts for that assembly are included in the same BOM. The parts breakdown for an assembly with any other KPN will be found in the BOM with the same number.

6. Unit of Measure (UM) Column

This column indicates the Unit of Measure for each part. Common abbreviations found in this column are listed below.

EA	Each
FT	Foot
AR	As Required

7. Quantity and Flavor Columns

Individual flavors of an assembly are identified by the last two digits of the KPN. Part quantities for each flavor will be indicated under headings numbered 00 through 99 as required. The parts indicated in the 99 Column are common to all other flavors of the assembly and are considered the Common Bill of Material for the assembly.

NOTES:

- I. ASS'Y OF HOLD DOWN UNIT AS FOLLOWS:
 - A. SLIDE IN SPREADER (047-4371-01) IN NOTCHES OF CHASSIS.
 - B. INSERT SCREW (089-6561-00) THRU CHASSIS & SPREADER & THREAD INTO HOLD DOWN (073-0379-02).
 - C. PLACE WASHER OVER SCREW AS SHOWN & PRESS IN PIN (090-0265-00).
 - D. BEND TABS OF SPREADER INTO GROOVES ON TABS OF MAIN CHASSIS.
2. -00 ASS'Y INCLUDES GLIDESLOPE WITH 012-1005-05 NECESSARY HARDWARE.
-01 ASS'Y IS WITHOUT GLIDESLOPE & ITEMS DESIGNATED WITH "*" ARE NOT USED.
3. SOLDER ONE END OF COAX TO E617 & E618, BRAIDED SHIELD GOING TO E618. PUT SHRINK TUBING (150-0049-10) OVER COAX WHERE IT PASSES THROUGH HOLE IN FENCE ON GLIDESLOPE BOARD. SOLDER OTHER END OF COAX TO E817 & E818, BRAIDED SHIELD GOING TO E818. COAX SHOULD BE APPROX. 7 1/4" LONG.
4. ALL SCREWS WITHOUT SELF-LOCKING FEATURE SHALL BE LIQUID STAKED.
5. USE 026-0003-00 BUS WIRE 089-5874-04(13) TO CONNECT J813 TO E619.
6. APPLY MYLAR TAPE (012-1005-05) AS SHOWN. TRIM TO CONTOUR.
7. INSERT GROMMET STRIP (091-0331-15), APPROX. 3/4" LONG, TO FINGERS ON COVER WHERE CABLE EXITS. BEND FINGERS ON COVER TO HOLD GROMMET STRIP.

NOTES:

1. ASSEMBLE 8 POSITION INC/DEC SWITCH AS SHOWN.
2. ATTACH SWITCH AND POT (03I-0353-0I) TO PC. BOARD BY BENDING TABS INWARD AND SOLDERING TO BOARD. SHOULDER OF TWO TABS SHALL BE FLUSH ON BACK SIDE OF PC. BOARD. PRIOR TO SOLDERING FIXTURE AS NECESSARY, TO MEET THE DIMENSIONS SHOWN BETWEEN CENTER LINE OF POT SHAFT AND CENTER LINE OF .615 DIAMETER OF LARGE KNOB WITHIN +.010.
3. SOLDER WIRES TO TWO TERMINALS ON SLIDE SWITCH (S206) NEAREST TO PC. BOARD.
4. SLIDE SWITCH BUTTON TO FIT BETWEEN TWO CIRCULAR SKIRTS OF KNOB (088-0866-0I).
5. SPRAY DETENTS WITH DRY LUBRICANT (016-1097-00) BEFORE ASSEMBLY. OVERSPRAY PERMISSIBLE.
6. AFTER ASSEMBLY, APPLY A SMALL AMOUNT OF EPOXY (016-1122-00) TO THE RETAINING RING (090-0036-04) TO SECURE IT TO THE SHAFT (088-0768-02).
7. ATTACH SWITCH TO BRACKET AS SHOWN BY SWAGING RIVETS ON BRACKET SURFACE.
8. SOLDER RED/WHT WIRE FROM E221 (BACKSIDE OF P.C. BD.) TO E220.

KING

KNS 81
APPENDIX "A"

1.1 GENERAL

Due to the wide utilization of semiconductors in this electronic equipment, somewhat different techniques are necessary in maintenance procedures. In solid state circuits the impedances and resistances encountered are of much lower values than those encountered in vacuum-tube circuits. Therefore, a few ohms discrepancy can greatly affect the performance of the equipment. Also, coupling and filter capacitors are of larger values and usually are of the tantalum type. Hence, when measuring values of capacitors, an instrument accurate in the high ranges must be employed. Capacitor polarity must be observed when measuring resistance. Usually more accurate measurements can be obtained if the semiconductors are removed or disconnected from the circuits.

1.1.1 SEMICONDUCTOR TEST EQUIPMENT

Damage to semiconductors by test equipment is usually the result of accidentally applying too much voltage to the elements. Common causes of damage from test equipment are discussed in the following paragraphs.

A. Transformerless Power Supplies

Test equipment with transformerless power supplies is one source of high current. However, this type of test equipment can be used by employing an isolation transformer in the AC power line.

B. Line Filter

It is still possible to damage semiconductors from line current, even though the test equipment has a power transformer in the power supply, if the test equipment is provided with a line filter. This filter may function as a voltage divider and apply half voltage to the semiconductor. To eliminate this condition, connect a ground wire from the chassis of the test equipment to the chassis of the equipment under test before making any other connections.

C. Low-Sensitivity Multimeters

Another cause of semiconductor damage is a multimeter that requires excessive current to provide adequate indications. Multimeters with sensitivities of less than 20,000 ohms-per-volt should not be used on semiconductors. When in doubt as to the amount of current supplied by a multimeter, check the multimeter circuits on all scales with an external, low-resistance multimeter connected in series with the multimeter leads. If more than one millampere is drawn on any range, this range cannot be safely used on small semiconductors.

D. Power Supply

When using a battery-type power supply, always use fresh batteries of the proper value. Make certain that the polarity of the power supply is correct for the equipment under test. Do not use power supplies having poor voltage regulation.

1.1.2 SEMICONDUCTOR VOLTAGE AND RESISTANCE MEASUREMENTS

When measuring voltage or resistance in circuits containing semiconductor devices, remember that these components are polarity and voltage conscious. Since the values of capacitors used in semiconductor circuits are usually large, time is required to charge these capacitors when they appear. Thus, any reading obtained is subject to error if sufficient time is not allowed for the capacitor to fully charge. When in doubt it may be best in some cases to isolate the components in question and measure them individually.

KING

KNS 81
APPENDIX "A"

1.1.3 TESTING OF TRANSISTORS

A transistor checker should be used to properly evaluate transistors. If a transistor tester is not available, a good multimeter may be used. Make sure that the multimeter meets the requirements outlined in the preceding paragraph.

A. PNP Transistor

To check a PNP transistor, connect the positive lead of the multimeter to the base of the transistor and the negative lead to the emitter or collector. Generally, a resistance reading of 50,000 ohms or more should be obtained. Reconnect the multimeter with the negative lead to the base. With the positive lead connected to the emitter or collector a resistance value of 500 ohms or less should be obtained.

B. NPN Transistor

Similar tests made on a NPN transistor should produce the following results:

With the negative lead of the multimeter connected to the base of the transistor the value of resistance between the base and the collector or emitter should be high. With the positive lead of the multimeter connected to the base, the value of resistance between the base and the collector or emitter should be low. If these results are not obtained, the transistor is probably defective and should be replaced.

CAUTION

IF A TRANSISTOR IS FOUND TO BE DEFECTIVE, MAKE CERTAIN THAT THE CIRCUIT IS IN GOOD OPERATING ORDER BEFORE INSTALLING A REPLACEMENT TRANSISTOR. IF A SHORT CIRCUIT EXISTS IN THE CIRCUIT, PUTTING IN ANOTHER TRANSISTOR WILL MOST LIKELY RESULT IN BURNING OUT THE NEW COMPONENT. DO NOT DEPEND UPON FUSES TO PROTECT TRANSISTORS.

C. Always check the value of the bias resistors in series with the various elements. A transistor is very sensitive to improper bias voltage; therefore, a short or open circuit in the bias resistance may damage the transistor.

1.1.4 REPLACING SEMICONDUCTORS

Never remove or replace a semiconductor with the supply voltage turned on. Transients thus produced may damage the semiconductor or others remaining in the circuit. If a semiconductor is to be evaluated in an external test circuit, be sure that no more voltage is applied to the semiconductor than normally is used in the circuit from which it came.

A. Use only a low heat soldering iron when installing or removing soldered-in semiconductors. Grasp the lead to which heat is applied between the solder joint and the semiconductor with long nosed pliers.

This will dissipate some of the heat that would otherwise be conducted into the semiconductor from the soldering iron. Make certain that all wires soldered to semiconductor terminals have first been properly tinned so that the necessary connection can be made quickly. Excessive heat will permanently damage a semiconductor.

B. In some cases, power transistors are mounted on heat-sinks that are designed to dissipate heat away from them. In some power circuits, the transistor must also be insulated from ground. This insulating is accomplished by means of an insulating washer made of mica. When replacing transistors mounted in this manner, be sure that the insulating washers are replaced in proper order. After the transistor is mounted and before making any connections, check from the case of the transistor to ground with a multimeter to see that the insulation is effective.

1.2 INTEGRATED CIRCUIT MAINTENANCE

1.2.1 GENERAL

A knowledge of integrated circuit fundamentals is as necessary in testing digital logic circuits involving IC's as a knowledge of rectification fundamentals is needed to test a power supply.

1.2.2 TERMINOLOGY

Several terms are used whenever logic circuits are discussed:

- A. A logic state is defined as a high or low level voltage applied to the input or seen at the output of a device. A high level voltage is called a logic "1". A low level voltage is called a logic "0". Logic threshold voltage of a device is the input voltage required at an input to change the output state.
- B. A truth table is a list of input logic states that will yield certain output logic states. A digital logic element should be thought of as a circuit element with its output level being either HI or LO as programmed by the levels present on its inputs.

A logic element may be tested by verifying that it is performing per the Truth Table of that logic element.
- C. Logic elements which have multiple inputs and a single output are known as gates. The OR gate produces a HI output when one or more of the inputs are HI. With all inputs LO, the output is LO. The AND gate produces a HI output only when all inputs are HI. When any input is LO the output is LO. A small circle at the output of a gate on the schematics indicates "negation", which means that the sense of the gate logic is reversed. An OR gate with negation is called a NOR gate and an AND gate with negation is called a NAND gate. A NOR gate produces a LO output when one or more of the inputs are HI and a NAND gate produces a LO output only when all inputs are HI.
- D. The Flip-Flop logic element is the basic data storage element of digital logic. It has two outputs that are always at opposite logic levels. That is, when one output is HI the other is LO. The Flip-Flop will remain in a particular state until that state is changed by an input signal.

The operation of these Flip-Flops is controlled by the signals on their inputs, and is best understood by a careful study of their Truth Tables. It should be kept in mind that a small circle on either the input or the output indicates negation. Also, a circle on a clock input indicates that a HI to LO transition causes the Flip-Flop to function.

- E. Besides the gates and Flip-Flops, two other commonly used logic elements are inverters and expanders. Inverters are merely switching transistors such that if a logic "1" is the input to a device, a logic "0" will be the output and vice-versa. An expander is a set of parallel switching transistors that depends upon another resistor to provide their supply voltage. Generally, these devices are used to expand the number of inputs available to a standard gate.

1.2.3 INTEGRATED CIRCUIT TEST EQUIPMENT

As with semiconductors, damage to integrated circuits by test equipment is usually the result of applying too much current or voltage to the elements. The same precautions as discussed in Paragraph 1.1.1 apply here.

1.2.4 VOLTAGE MEASUREMENTS

Precise voltage measurements are not needed in testing digital IC's other than to see that the voltage is a HI or a LO level. An oscilloscope is needed where the input levels are of short duration, either HI or LO. For instance, if a 10 microsecond pulse going from LO to HI was applied to one input of a NOR gate, while the other input stayed LO, the output would go LO for 10 microseconds and then return HI. This, of course, could not be seen without an oscilloscope.

KING

KNS 81
APPENDIX "A"

1.2.5 TESTING INTEGRATED CIRCUITS

The fully loaded guaranteed minimum high and maximum low for the digital logic output levels are:

TTL ($V_{cc} = +5V$)		ECL ($V_{cc} = +5.2V$)	
High	Low	High	Low
2.4	0.5	4.25	3.48

The minimum high and maximum low input levels which are guaranteed to be correctly interpreted are:

TTL ($V_{cc} = +5V$)		ECL ($V_{cc} = +5.2V$)	
High	Low	High	Low
2.0	0.8	4.06	3.75

When checking input and output levels of a logic element under question, it should be remembered that an input or output may not agree with its truth table not because it has malfunctioned but because some other component connected to the same point has shorted to ground or to the supply voltage (V_{cc}). This is not common when an output on one element is connected to an input of another. A majority of digital IC failures can be grouped into three categories:

- A. Input(s) or output shorted to ground pin of I.C.
- B. Input(s) or output shorted to V_{cc} pin of I.C.
- C. Open input(s) or output

An input or output to ground would be constant LO and an input or output shorted to V_{cc} would be constant HI.

Other failures common in digital IC's are:

- A. Ground pin open.
- B. V_{cc} pin open.
- C. Inputs shorted together.

An open ground pin would not allow a LO on the output. An open V_{cc} pin would not allow a HI on the output. (Remember to isolate the device from other components connected to it.). Two or more inputs shorted together can be checked by grounding one of the inputs under question. If the other input also goes to ground, they are probably shorted.

CAUTION

IF AN IC IS FOUND TO BE DEFECTIVE, VERIFY THAT PROPER POWER SUPPLY VOLTAGES ARE PRESENT BEFORE INSTALLING A REPLACEMENT IC.

1.2.6 REPLACING INTEGRATED CIRCUITS

If an IC is known to be defective, the easiest way to remove it is to cut off each of its pins, remove the case, and then unsolder the remaining pins from the printed circuit board one by one. This is preferable over removing the IC intact because attempts to remove the IC intact may result in damage to the printed circuit board.

120-0089-00

HIGH VOLTAGE CATHODE DECODER/DRIVER

GENERAL DESCRIPTION

The DS8884 is designed to decode four lines of BCD input and drive seven-segment digits of gas-filled readout displays. Two separate inputs are provided for driving the decimal point and comma cathodes.

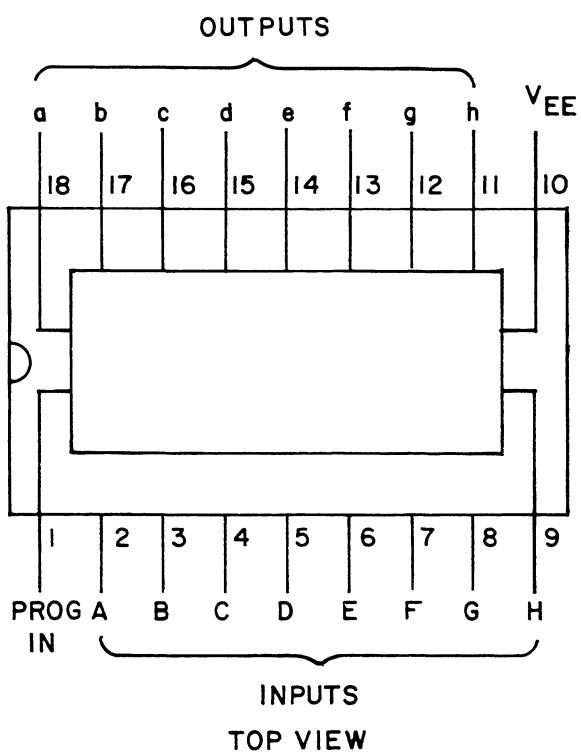

All outputs consist of switchable and programmable current sinks which provide constant current to the tube cathodes, even with high tube anode supply tolerance. Output currents may be varied over the 0.2 to 1.2ma range for multiplex operation. The output current is adjusted by connecting an external program resistor (R_p) from V_{cc} to the program input in accordance with the programming curve.

120-2028-00

TOP VIEW

1400 Bit Electrically Alterable Read Only Memory

DESCRIPTION

The ER1400 is a serial input/output 1400 bit electrically erasable and reprogrammable ROM, organized as 100 words of 14 bits each. Data and address are communicated in serial form via a one-pin bidirectional buss.

Addressing is by two consecutive one-of-ten codes.

Mode selection is by a 3 bit code applied to C1, C2 and C3.

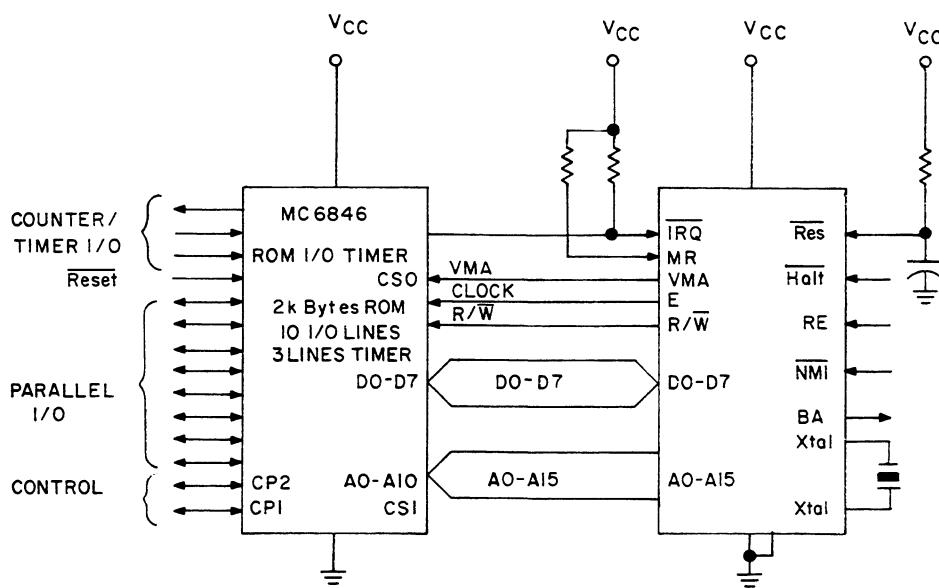

Data is stored by internal negative writing pulses that selectively tunnel charge into the oxide-nitride interface of the gate insulator of the 1400 MNOS memory transistors. When the writing voltage is removed the charge trapped at the interface is manifested as a negative shift in the threshold voltage of the selected memory transistors.

MC 1709CP
120-3001-00

IC, OP AMP

This device circuit is a high-performance operational amplifier with high-impedance differential inputs and a low-impedance output. Component matching, inherent with silicon monolithic circuit fabrication techniques, produces an amplifier with low drift and offset characteristics. Provisions are incorporated within the circuit whereby external components may be used to compensate the amplifier for stable operation under various feedback or load conditions. These amplifiers are particularly attractive for applications requiring transfer or generation of linear or non-linear functions.

MC1350P

120-3020-00

MONOLITHIC IF AMPLIFIER

...an integrated circuit featuring wide range AGC for use as an IF amplifier in radio and TV over the temperature range 0 to +75°C. The MC 1352 is similar in design but has a keyed-AGC amplifier as an integral part of the same chip.

Power Gain - 50dB typ. at 45MHz,
- 48dB typ. at 58MHz

AGC Range - 60dB min, DC to 45MHz

Nearly constant input and output admittance over the entire AGC range

Y_{21} Constant (-3.0dB) to 90MHz

Low Reverse Transfer Admittance - 1.0umho typ.

12-Volt Operation, Single-Polarity Power Supply

APPENDIX "A"

LM1458P
120-3022-00

GENERAL DESCRIPTION

The LM1458 and the LM1558 are general purpose dual operational amplifiers. The two amplifiers share a common bias network and power supply leads. Otherwise, their operation is completely independent. Features include:

No frequency compensation required

Short-circuit protection

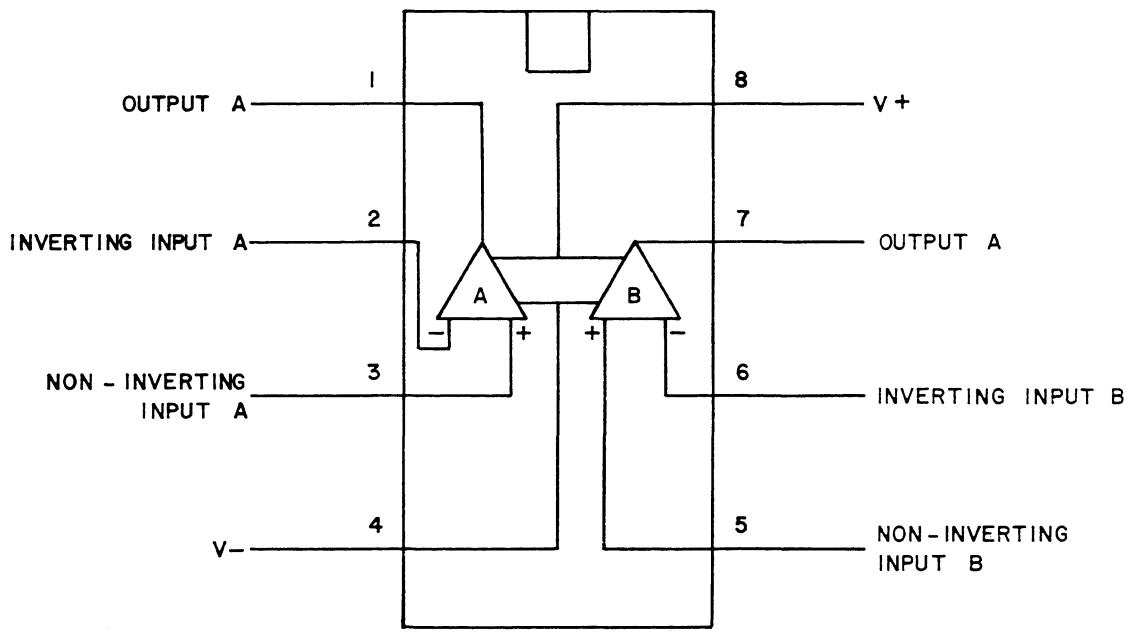

Wide common-mode and differential voltage ranges

Low-power consumption

8-lead TO-5 and 8-lead mini DIP

No latch up when input common mode range is exceeded

The LM1458 is identical to the LM1558 except that the LM1458 has its specifications guaranteed over the temperature range from 0°C to 70°C instead of -55°C to +125°C.

functional block diagram

LINEAR INTEGRATED CIRCUITS

DESCRIPTION

The NE/SE 555 monolithic timing circuit is a highly stable controller capable of producing accurate time delays, or oscillation. Additional terminals are provided for triggering or resetting if desired. In the time delay mode of operation, the time is precisely controlled by one external resistor and capacitor. For a stable operation as an oscillator, the free running frequency and the duty cycle are both accurately controlled with two external resistors and one capacitor. The circuit may be triggered and reset on falling waveforms, and the output structure can source or sink up to 200ma or drive TTL circuits.

KNS 81
APPENDIX "A"

LM339N

120-3048-00

The LM339 consists of four independent voltage comparators which were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage. These comparators also have a unique characteristic in that the input common-mode voltage range includes ground, even though operated from a single power supply voltage.

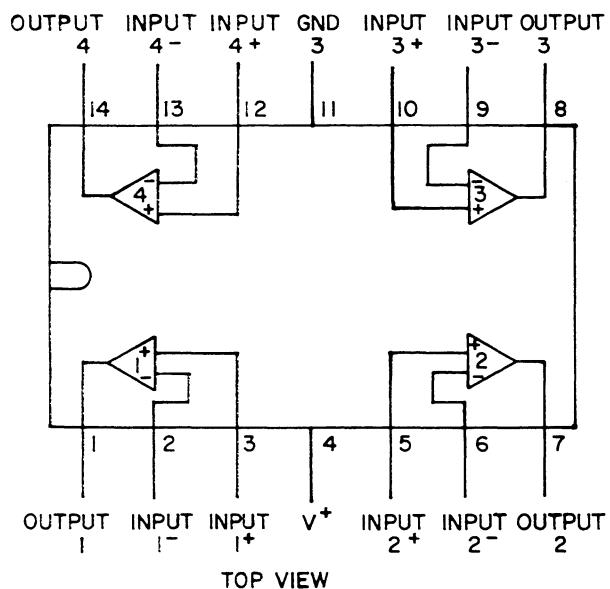

Dual-In-Line and Flat Package

LM 324

120-3052-00

DUAL-IN-LINE AND FLAT PACKAGE

GENERAL DESCRIPTION

This series consists of four independent, high gain, internally frequency compensated operational amplifiers which were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage.

Application areas include transducer amplifiers, DC gain blocks and all the conventional op amp circuits which now can be more easily implemented in single power systems. For example, this series can be directly operated off of the standard +5VDC power supply voltage which is used in digital systems and will easily provide the required interface electronics without requiring the additional +15VDC power supplies.

I.C., PRECISION VOLTAGE REFERENCE

This series of three terminal positive regulators is available with several fixed output voltages making them useful in a wide range of applications. The regulators have $\pm 2\%$ V_{OUT} specification, 0.04%/V line regulation, and 0.01%/mA load regulation. When used as a zener diode/resistor combination replacement, the regulator usually results in an effective output impedance improvement of two orders of magnitude, and lower quiescent current. These regulators can provide local on card regulation, eliminating the distribution problems associated with single point regulation. The voltages available allow it to be used in logic systems, instrumentation, HI-FI, and other solid state electronic equipment. Although designed primarily as fixed voltage regulators, these devices can be used with external components to obtain adjustable voltages and currents.

With adequate heat sinking the regulator can deliver 100mA output current. Current limiting is included to limit the peak output current to a safe value. Safe area protection for the output transistor is provided to limit internal power dissipation. If internal power dissipation becomes too high for the heat sinking provided, the thermal shutdown circuit takes over, preventing the IC from overheating.

CD4001
120-6002-00/01
QUAD 2- INPUT NOR GATE

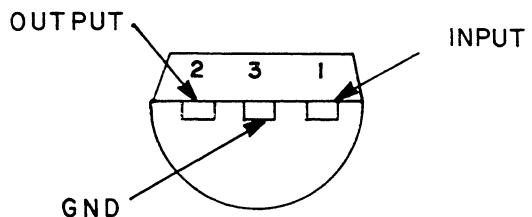

This device is a monolithic quadruple two-input NOR gate. N and P-channel enhancement mode transistors provide a symmetrical circuit with output swings essentially equal to the supply voltage. This results in high noise immunity over a wide supply voltage range. No DC power other than that caused by leakage current is consumed during static conditions. All inputs are protected against static discharge and latching conditions.

NC=NO CHANGE

This device is an 18-stage static shift register which is comprised of four separate "shift register" sections, two sections of four stages and two sections of five stages. Each section has an independent data input. A common clock signal is used for all stages. Data is shifted to the next stage on the negative-going transition of the clock. Through appropriate connections of input and outputs, multiple register sections of 4, 5, 8, and 9 stages or single register sections of 10, 12, 13, 14, 16, 17, and 18 can be implemented by using one device. Longer shift register sections can be assembled by using more than one device.

SCL4013
120-6009-01

CD4013A types consist of two identical, independent data-type flip-flops. Each flip-flop has independent data, set, reset, and clock inputs and "Q" and "Q̄" outputs. These devices can be used for shift register applications, and, by connecting "Q̄" output to the data input, for counter and toggle applications. The logic level present at the "D" input is transferred to the Q output during the positive-going transition of the clock pulse. Setting or resetting is independent of the clock and is accomplished by a high level on the set or reset line, respectively.
